A

Aarons, Dr. S. Jervois, specimens of four cases of membranous dysmenorrhœa, 512

Abattoir (municipal) at Marseilles, 1250; model, at Basle, 1522; Paris, at La Villette, 254

Abattoirs, public and municipal, at Amsterdam, 653; Basle, 1365; Constantinople, practices in, 1250; Frankfort and Homburg, 537; Gibraltar, 547; Lisbon, 633; Milan, 613; Monaco, 547; (O. L. Robinson), 764; Paris, at La Villette, 123; Scotland question regarding in Parliament, 1472; Vercelli, 613

Abdomen, distension, acute, of, in intraperitoneal bleeding from uterine fibroid (Mr. W. Bruce Clarke), 8; operations on, factors of success in, 1161; pain in, early differential diagnosis of, 1037; surgery of conservative (C. B. B. Keetley), 1761; tumour of, 839; associated with disease of the testicle (Prof. W. Osler), 1499

"Abdominal conflux, acute," area of, in relation to "incision of incidence" (Mr. C. P. Childe), 936; disease, difficulty of diagnosis in, shown by two cases of, 740

Abercrombie, Dr. P. H., thyrotomy for epithelioma of (1) right vocal cord, (2) left vocal cord, exhibition of cases, 812; "Tuberculoid" disease of left tonsil, exhibition of case of, 812

Aberdeen, death-rate among infants, low, 1514; immunity from small-pox, 1526; medical questions at Trades Congress held at, 1255; public health matters at, 1746; school children of, diseases of eye in, 1156; water-supply for, 1677

Aberdeen Royal Infirmary, 1256; donation to, 1193

Aberdeen University, Anatomical and Anthropological Society, 1526; pass list, 1126

Aberdeenshire, cerebro spinal fever in, 1556

Aberystwyth, public health in, 639

Abortion among the ancients, 172, 325; in Paris, discussion on, 1257

Abortionists' houses designated "public nuisances" by New York State, 1614

Abrahams, Dr. B. L., the Arris and Gale lecture on the permanent defences of the body, delivered before the Royal College of Surgeons of England on Feb. 22nd, 1907, 761; unusual case of enlargement of the head in a male child, 292; case of inoperable cancer treated with trypsin, 360

Abram, Dr. J. Hill, case of cleido-cranial dysostosis (Marie and Sainton), 663

Abrams, Dr. A., amyl-nitrite in hæmoptysis, 117, 320

Abscess, new method of treating (Mr. Joseph Lister [Lord Lister]: Looking Back), 862; cerebellar, specimen exhibited, 1020, 1021; cerebral, case of, 550; extra-dural, case of, 1364; multiple, 1163; otitic cerebral, with meningitis, 1654; para-appendical, accompanying pelvic appendicitis (Mr. G. Barling), 1345; pelvic, due to appendicitis, 1576; periosteal, bacillus typhosus from, one year after typhoid fever, 571; pulmonary, and acute endocarditis, complicating acute pneumonia, 169; treated by administration of creasote, 1021; of spleen, 1517, (Dr. R. H. Lucy) 1775 (see also Psoas abscess)

Abstinence, complete, remarkable case of (Looking Back), 185

Academy of Medicine, Paris, gift to, 1046; Toronto, amalgamation of medical societies, 917

Accidents, compensation for: Workmen's Compensation Act (1906) (leading article), 240; insurance against by medical men, 1678; fatal, in factories and workshops during 1905, published by Home Office, 527

Accidents (see also Street accidents)

Accoucheurs, municipal, of Constantinople, gratuitous treatment of, 1259

Accounts, medical, curiosity in, 651

Accrington Hospital extension, 913

Acetone, detection of, in urine, 824, 911; in urine, tests for (Mr. B. Jacksontaylor), 805

Aceto salicylic acid in rheumatic endo-pericarditis (Dr. E. C. B. Ibotson), 732

Acetonuria, clinical significance and treatment, 511

Achondroplasia, case, 292

Achromatic illuminator, 1718

Acidity of urine, 340

Acrodermatitis hiemalis, case of, 295

Acromegaly, case of, 292; exhibited, 512

Actinomycosis, 891; case of, exhibited, 741

Adam, Mr. J., fibromyoma of the ovary (shown by Dr. McGregor), 232; localisation of general paralysis of the insane, 1115; exhibition of cases (1) of atrophic rhinitis, (2) of tuberculous lesion of various regions, (3) of chronic adenoma of face, 1364

Adamson, Dr. H. G., reddened, shiny, soft congenital tumour, diagnosis as mole, 1165

Addenbrooke's Hospital, Cambridge, convalescent home of, appeal for aid, 1513

Addenzell, Mr. W. A., presentation to, 390

Addinsell, Dr. A. W., on metritis, 1654

Addison (W., M.D.), the world's first hæmatologist (Dr. Hugh McCallum), 182

Addison's disease, case occurring in child, 1163; diagnosis of, 1158

Adelaide, Kalyra Sanatorium, 109; Hospital, Dublin, 1193

Adenoma of face, chronic, 1364

Adiposis dolorosa associated with myxœdema, 1017

Adler, Dr., torsion of the omentum, 1517

Adrenalin, influence on heart and vessels, 1739; and eucaine tablets, 33

Adulteration of cider, 839; of food in Vienna, 1259; of milk and butter in Australia, 621; of Wines, Spirits, and Beer, its Effect on Health, Conference on, 1244 (see also Food-stuffs)

Advertisements of the Evans Vacuum Cap Company, 403; indecent, responsibility of editors in respect to (leading article), 100; offensive, suppression in comic paper, *Judy* 180; of quacks, 701, 651; misleading character of, 203; in *Pick-Me-Up*, 701; quantity sent to medical profession by post, 329

Advertisements Regulation Bill, 1193

Advertising by unqualified dentists, 1099; public abuses of, 701

Advisory Board, appointment of, in connexion with Army Medical Services (leading article), 56; reconstructed, 178, 187

Aequanimitas (Prof. W. Osler) (review), 95

Affleck, Dr. J. O., the prognosis and treatment of lobar pneumonia, 808

Afflicted children in Ireland Bill, 848

Africa (North), climates and mineral water health resorts of (climatotherapy and balneotherapy) (Sir H. Weber and Dr. F. Parkes Weber) (review), 435; South, leprosy in, announcement of discussion on, 181; tuberculosis problem in, 1559; unsound food returned from, 1100; see also South African exhibition; German S.W. settlements for tuberculous patients in, 619; West, health and sickness in, 58; medical service of, 120, 201, 1332; West Coast of, suggestions for health and sanitation on, 391

African Tick Fever, Parasite in, Experimental Study (review), 28

After-Care Association, 475; for poor persons discharged recovered from asylums for the insane, 1031

After cataract, treatment, 1574

Age-incidence of mortality from certain diseases, variations in (Sir S. Murphy), 1566

Age, old (see Old age)

Agglutination reaction absent in case of diagnosis of typhoid fever by blood culture, 163

Agriculture, discovery of method of obtaining nitric acid from air for purposes of, 245

Ague: brass-founders', 1725; "leaping ague of Angusshire" (Looking Back), 1302

Ailments, Common, Avoidance of, How to Keep Well (Dr. C. S. Read) (review), 32

Air, atmospheric, discovery of method of obtaining nitric acid from, for agricultural and industrial purposes, 245; effect of cooking by gas-stoves on purity of, 1460; purification of by fall of snow, 39; of the Stock Exchange, impurity of, 1783; rapid displacement of, in motoring, influence on general nutrition, 1815

Air embolism, heart failure due to, 1247; fatal from puncture of liver with aspirating needle, 1182

Air purifier, new, 839

Alara, 1169

Albany, Duchess of, visit to Royal Free Hospital, 791; visit to Liverpool School of Tropical Medicine, 257

Albinism in man, 998

Albrecht, Dr. Paul, case of fistula after thyroiditis, 230

Albumin, digestion of, in body, 1740

Albuminuria complicating pregnancy, 511; treatment, 1494; (acute) caused by pressure of tumour on both ureters, 169; see also Nucleo-albuminuria

Albuminous bodies present in pathological effusions, 1513; (Dr. W. Cecil Bosanquet), 1360

Albumosuria, myelopathic, simulated by nucleo-albuminuria, 1353
Alcohol and the Human Body (Sir V. Horsley and Miss M. D. Sturge) (review), 1714; duty on, remission suggested for medical purposes, 40, 190; indulgence in, causing traffic accidents, 1630; injections of, in treatment of neuralgia, 1535; Italian physicians on, 1663; in medicine, use of, 192; nutritional character and therapeutic uses of, 512; Sanction for the Use of (Dr. J. Starke) (review), 1222; and infants, question regarding, in Parliament, 921
Alcohol (see also Beverages, alcoholic)
Alcoholism, acute, death due to, after drinking from old rum casks, 1744; decrease of, in Budapest, 60; experimental studies in, 1504; in United States navy, 696
Aldershot, hospital accommodation at, question in Parliament, 1494; sewage farm, 643
Aldrovandi, Ulisse, tercentenary of, 1453, 1807
Alexander, Dr., modern treatment of thrombosis of lateral sinus, 1816
Alexander, Mr. G. P., death of, 1814
Alexander, Dr. W., rupture of the spleen: splenectomy; recovery, 90; aseptic and septic midwifery at the Liverpool workhouse infirmary, 940
Alexandra, H.M. Queen, committee for Jubilee Institute for Nurses, 1681
Algeria, vaccination in, 1678
Algiers, British Cottage Hospital, appointment of medical officer, 340
Alginoid copper (cupralgin), 32
"Algiron," 1052
Aliens, rejection of, 1403
Alkali, caustic, in estimation of sugar in urine, 1446
Alkaloid in fresh valerian juice, pharmacology of, 900
Alkaptonuria, new case of, 650
Allan, Mr. A. P., The true aim of medical education, 823
Allan, Dr. G. A., Primary cancer of a bronchus, 1364
Allan, Dr. J., Surgeon's power of life and death, 762
Allbutt, Prof. Clifford, portrait of, for Leeds Infirmary, 467; "Prodromata," 452
Allen, Dr. R. W., Pembrey, Dr. M. S., and Pitt, Dr. G. Newton, Observations on case of Cheyne-Stokes respiration, 91
Alopecia, syphilitic, 1229
Amalgamation of London medical societies, 1601; meeting to decide name, 457; name of new society, 445, 521; position of Medical Society of London in relation to, 821; of Medical Society of Victoria and Victorian Branch of the British Medical Association, 620
Amat, M., Influence of vaccination on whooping-cough, 1398
Amateur physicians in the past, 446
Ambulance (see Green Cross, Red Cross, Volunteer Ambulance School of Instruction)
Ambulance service of City of London, 1373; electric motor, 1331; (see also Metropolitan Street Ambulance Service)
Ambulance vans (see Motor ambulance vans)
Amenorrhœa, primary, caused by tuberculous disease of uterus and appendages, 1161
Amentia, so-called Mongolian type of, congenital deformities of, 295; (see also Imbecility)
America, law of insanity in, in relation to crime, 381; (Central) Diseases of (Dr. T. W. Jackson) (review), 1655; surgery in (C. H. Whiteford), 1577
American Association for the Advancement of Science, President of, 375; companies, offer of secret commissions to medical men by, 1473; republics, international sanitary arrangements of, 135; review of orations before (leading article), 1658
American Medical Association, council on pharmacy and chemistry, 982; and proprietary medicines (leading article), 1695; action with regard to medicinal foods, 1615; tinned meats, 1681; suits, pressure paralysis as an accident and expectancy of life, 607; Urological Association, tribute to the memory of the late W. K. Otis at, 46
American Association for the Promotion of Hygiene in Schools, 1615
Ames, Dr. J. L., A case of poisoning by nitrobenzene, 1029
Amnesia, case of (Looking Back), 1671
Amputation, Pirogoff's modified, in men, 1826; spontaneous, of appendix vermiformis in sac of femoral hernia, 244; through thigh for gangrene of leg with diabetes, recovery, 1494
Amsterdam, municipal abattoir at, 683
Amyl nitrite in treatment of hæmoptysis, 117, 328; (Dr. Francis Hare), 189; (Dr. G. A. Crace Calvert), 939
Anæmia and enlarged spleen accompanying periarthritis (Still's disease), 155; pernicious, and ascaris lumbricoides, gregarinosis in man, 51; splenic, occurring in a man, 1162; infantum, cases exhibited, 1161, 1162; in subject of hereditary syphilis, 1162
Anæsthesia, experimental (leading article), 1304; local, induction of, by cocaine cataphoresis, 909; in General Surgery (Mr. J. W. Struthers) (review), 235; spinal, with stovaine, 45; in surgery of children, 234
Anæsthetics and their Administration (Dr. F. W. Hewitt) (review), 513; general, administration of, method in Budapest surgical clinics, 374, 395; Practical Handbook (Dr. J. Blomfield) (review), 1089; Uses and Administration (Dr. Dudley W. Buxton) (review), 1022
Anastomosis, ileo-sigmoid lateral, in treatment of intestinal obstruction with ascites, 1021
Analysis, Qualitative, Principles of (W. Böttger) (review), 1717

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Adrenalin and eucaine tablets, 33—Alaxa, 1169—Bananine cocoa, 441—Biscols (Frandin), 745—Calyx phosphatic corn-flour, 1783—Cerebos salt, 745—Cathartic compound, 1723—Charcoal biscuits, 441—Chloroform, 1723—Cigarettes, Turkish (Sackville brand), 1170—Clos des cordeliers (sparkling), 1169—Cold cream, 1438—Cupralgin, 32—Curry powder, 745—Cyder, 1170—Cylin (medical), 33—Desiccated soups, 1437—Domecq's brandy, 33—Elixir of formates, 34—Elixir heroin and terpin hydrate, 33—Elixoid pine tar compound, 1437—Ernutin, 1783—Esencia de Calisaya, 33—Ether, 1783—Exsiccated egg products, 745—Foods for the diabetic, 745—Fibro-mangan preparations, 1782—Formidine, 1783—Goats' milk, 1437—Graphic club cigarettes, 1438—Hydroliths, 440—Iodalbin, 1169—Kerol, 33—Lubricant, sterilised, 1169—Lymm pure salt, 440—Malt and hæmoglobin, 34—(1) Marvis fish flakes, (2) malted marvis, 33—Moselle grape-juice, 1169—Mutton essence, 441—Nauheim bath salts, 440—Oatmeal stout, 1783—Okol disinfectant, 441—Non-alcoholic beer, 1783—Oxylithe, 440—Peptone, nutritive liquid, 1169—Perboral, 440—Phenofax, 33—Phenolphtalein compound, compressed tablets, 1169—Piperazine, effervescent (Midy), 1169—Plasmon bread, 1438—Port (Mr. Jorrock's brand M.F.H. special), 440—Quinine acetyl salicylate, 1169—Regulin, 1782—Saline laxative (effervescent), 1783—"Sancol" grape juice, 1437—Sauterne, 1437—"Solace" shaving soap, 33—Soloid eosin-azur, 33—Soloid nizin, 1437—Soluble bismuth citrate, 744—Soluble iron arsenate, 744—"Tabloid" pectoral pastilles, 440—"Tabloid" calcium lactate, 440—"Tabloid" xaxa and combinations, 744—Tilia food preparations, 744—Triple glycerophosphates with nuclein, 1783—Typhoo tea, 1438—Unbleached flour, 440—Vegetable butter "palmine," 745—Vest pocket inhaler, 33—Villacabras mineral aperient water, 441—Virag mineral water, 33—White voslauer goldeck and sparkling goldeck, 1783

Anastomosis, facio-hypoglossal, for post-operative paralysis, 584
Anatomical and Anthropological Society of the University of Aberdeen, proceedings, 1904–05 (review), 893
Anatomy, Applied (Topographical), Atlas of (Dr. K. von Bardeleben and Prof. H. Haeckel) (review), 298; lectureship in, established, at Glasgow University, 550; Human, Atlas and Text-book (Prof. J. Sobotta and Prof. J. P. McMurrich), 1366; Progress in, Practical Medicine Series, vol. ix. (review), 1368; Systematic and Practical, including Embryology (Dr. A. M. Buchanan) (review), 1496; teaching of, in Dublin, 1256
Ancients, abortion among, 176, 325
Anderson, Mr. A. R., a specimen of true papilloma of bladder, 232; uterus with contained fœtus and placenta, 232
Anderson, Dr. T. L., and Cleland, Dr. J. Burton, the transmission of plague, 974
Anderson Berry, Dr. D., marine climates in treatment of tuberculosis, 893
Anderston, health association for, proposed, 68, 393
Andrew, Mr. J. G., two cases of traumatic rupture of the kidney, in one of which a single kidney existed, 213
Andrewes, Dr. F. W., observations on MacConkey's bile salt neutral red medium, 167
Andrews, Dr. H. Russell, Midwifery for Nurses (1906) (review), 1023; two cases of pregnancy in a rudimentary uterine horn, 1662
Aneurysm, by anastomosis, treatment by vaccination (Looking Back), 1454; aortic, 741; cases, 1077, 1150; of third part of arch, 1229; femoral, excision; cure (Mr. B. Pollard), 1155; of innominate artery, 285; operations for, 1321; of ophthalmic artery cured by gelatin, 915; of orbit, arterio-venous (Major C. G. Spencer), 1025
Angus-shire, "leaping ague of" (Looking Back), 1352; popliteal, traumatic, case of (Mr. C. R. Keyser), 165
Aniline dyes, staining of fat with, 225
Animals, immunised, glandular extract from, as a curative agent in plague (Dr. S. Mallannah), 222; living, Home Office report of experiments on, in 1905, 1522; lower, demonstration on diseases of, 914; tuberculosis of, in relation to human tuberculosis (leading article), 353
Ankylosis of both hips and knees, due to gonorrhœal arthritis, 1021; rheumatic, case treated by Heusing's apparatus and elastic traction, 1021
Ankylostomiasis in Belgium, 602
Annals of Otology, Rhinology, and Laryngology (Fraenkel Festschrift number) (review), 598
Annals of Tropical Medicine and Parasitology, vol. i., No. 1 (review), 1368
Annual reports of medical officers of health influenced by security of tenure of office (leading article), 818
Anschütz, Dr., resection of the liver, 1517
Antarctic soil, bacteriology of, 1614
Anthrax, cases of, 1394; question regarding, in Parliament, 1199; danger of, from hair and bristles, 1726; deaths from, 395, 914, 1610; in Vienna, 845; local, complicated by pneumonia, 1178; notification of, at Liverpool, 1813; suspected, medical inspection for at Liverpool, 1525; treatment by iodine, 197
Anthropology (physical) at University of Liverpool, 839
Anthropometric survey, suggestion for (leading article), 895
Antibodies of Toxins and Venoms (E. P. Ecot) (review), 655
Anti-colon bacillus serum, value of, 1094
"Antigone," performance of, at Bradfield College, 1725
Anti-malaria campaign (see Malaria, campaign against)
"Anti-opium" plant, 557; remedy, 1335
"Anti-sephone," description of, 852
Anti-serum (see Diphtheria anti-serum)
Antistreptococcic serum (see Serum, antistreptococcic)
Antitoxin, quantitative relationship between globulin and antitoxin of diphtheria antiserum, 225; of syphilis in cerebro-spinal fluid, 618; in treatment of diphtheria, results, 1396
Anti-tryptic power of blood-serum, 169
Antivaccinationists, Heywood as a refuge for, 57; misrepresentations of, 1657
Antrim Infirmary, Lisburn, 1461
Aorta, aneurysm of third part of arch of, 1229; two cases, 692; rupture of (Dr. R. A. Forster), 683
Apart, M., the thyroid treatment of infantilism, 1527
Aphasia, treatment of, 1740; motor, with left hemiplegia, case exhibited, 1161; with right hemiplegia, 1163
Aphemia, case of, exhibited, 1163
Apoplexy, singular affection of speech due to (Looking Back), 668; treatment of, 1161
Apothecaries of eighteenth century, virtues of, 822
Apothecaries' Hall of Ireland, 1677; annual dinner, 550; examiners appointed, 1510; motion regarding defeated at General Medical Council, 1510
Appendages, uterine, operations on, technique, 510
Appendicitis, acute, diagnosis of, 1019, 1020; treatment of, 691, 1019, 1020; co-existence with intestinal obstruction 947; complicating typhoid fever (Mr. C. Leedham-Green), 356; pelvic abscess due to, 1376; pelvic, accompanied by par-appendical abscess and cystitis (Mr. G. Barling), 1345; simulated by surgical affections of right iliac fossa, 1159; suppurative, fæcal fistula, following, 1431
Appendicostomy for dysenteric ulceration of large intestine, 427; in treatment of ulcerative colitis, 1227
Appendix, amputation of, spontaneous in sac of femoral hernia, 244; cancer of, 130; gall-stones in (Dr. H. A. Leilard), 83; inversion of, 54; lymphatic system of (Dr. J. Kay Jamieson and Mr. J. F. Dobson), 1137; pain in, acute and chronic, medical and surgical treatment (Dr. St. R. Bonnet), 1425; removal of, cure of muco-membranous enterocolitis by, 1461; surgery, conservative of, and its relation to surgical treatment of chronic constipation (Mr. C. B. B. Keetley), 1761

Appenines, dangers from frost and wolves during winter, 571
Appointments, weekly list of, 64, 135, 202, 264, 333, 402, 476, 555, 628, 693, 776, 850, 922, 989, 1055, 1130, 1201, 1263, 1334, 1404, 1472, 1538; various, 128, 523, 693, 936, 1622, 1637, 1762, 1824; Lieut.-Col. C. E. Harrison, 1312
Arabs, blindness among, 59
Arany, Dr. S. A., some points in diabetes, 521, 687
Arbroath Infirmary, 1610; appreciation of services in Elliot railway disaster, 393
Archer, Dr. Launcelot, question of professional procedure, 404
Archer-Brown, Dr. E., typhus fever in Teneriffe, 325
Architectural Association, date of meeting, 771
Ardler (Perthshire), water-supply, question regarding in Parliament, 843
Argemone Mexicana, 629
Argyllshire, gift of sanatorium for, 393
Argyrol, efficiency in treatment of acute mucopurulent conjunctivitis compared with that of silver nitrate and protargol, 525; in ophthalmic practice, uses and limitations, 1603
Aristolochia cymbifera, medicinal action of, 243
Arkwright, Mr. Edwyn, the British Cottage Hospital, Algiers (appointment of medical officer), 340
Arm, dorsal displacement of, in vertex presentation (Dr. A. G. Wells) 165, 462
Arm and left hand, weakness and wasting of muscles of, 94; left, congenital absence of, 1163; Erb's paralysis of, in infant, due to difficult labour, 1165; spastic paresis of, with cyanosis in hand, 423
Armit, Mr. H. W., chemical researches on the toxic actions of iron and nickel, 226
Armitage, Mr. F. P., A History of Chemistry (review), 949
Armour, Mr. D. J., removal of polycystic kidney, 835

Butter: adulteration of, in Perth, Australia, 621—prosecution for, quashed, 1193; legislation in regard to, 699; sale of, prosecutions in Bath, question regarding, in Parliament, 1128; vegetable, "palmine," 745; Bill, 774
Butter and Margarine Bill, 523, 553, 625, 1193, 1255, 1403, 1536, 1618; (Parliamentary question), 1622
Button and book carding, 390
Buxton, Dr. D. W., Anæsthetics: their Uses and Administration, fourth edition, 1907 (review), 1022
Buzzard, Dr. E. F., abstract of the Goulstonian lectures on certain acute infective or toxic conditions of the nervous system, delivered before the Royal College of Physicians of London, 705, 785, 863; (leading article on), 1025

C

Cabot, Dr. R. C., Case Teaching in Medicine, 1906 (review), 1435
Cactus grandiflorus, therapeutic value of, 753
Cæcostomy in treatment of ulcerative colitis, 1227
Cæcum and ascending colon, resection for tuberculous stricture, 94
Cæcum, lymphatic system of (Dr. J. Kay Jobson and Mr. J. F. Dobson), 1157; malignant disease of, diagnosis and treatment, 170; volvulus of entire small intestine, cæcum, and ascending colon, 977
Cæsarean section: successful delivery by, 1035; use of iodised catgut for suture of uterine wall, 271; vaginal, cases, 1713
Cairo, water-supply of, 671
Caisson disease, 225
Calcar femorale, arrangement in upper end of femur, 559
Calcium chloride: antitoxic rôle of, in Bright's disease, 841; internal administration of, successful in treatment of ulcer of leg, 512; in treatment of urticaria, 1120; salts as cardiac tonic (Mr. J. Stark), 1710
Calculi: encysted in right kidney, exhibited, 512; sublingual, multiple, 427; vesical, large, 1315; large, specimens of, 1534
Calculus, cystine, specimens of, 663
Calculus, renal, cases of, 1365; diagnosis, 948; diagnosis by x rays, 948; rare case, 695
Calculus, salivary, tuberculous gland in, mistaken for, 231
Calculus, ureteral, three inches long, and three quarters of inch in diameter, 1229
Calculus, vesical, largest specimens removed by operation, 546, 1604; removal of, methods for, 610; successfully removed by suprapubic operation (Mr. H. Littlewood), 422; with nucleus of pedicle silk, 94
Calculus, ureteral, cases of, 1355; removed by parasacral incision, 1021; removed from each ureter for double pyonephrosis, 295
Calcutta: evil of cocaine drinking in, 1123; plague department in, 1393; precautions against plague in, 1254; seven days' fever of, 69
Caldwell, Mr. F., warrant for arrest of "Leonard de Bayer," 1475
Caldwell, Mr. William, estimation of urea and hydroxybutyric acid in urine, 509
Caledonian Medical Journal (review), 98, 1253
Calendar, historico-medical, 62
Caley, Dr. H. A., aneurysm of the innominate artery (case shown by Dr. F. Langmead), 295
Calico causing blood poisoning, question regarding, in Parliament, 1257
Callipers for frontal sinus probe, 517
Callard and Co., foods for the diabetic, a correction, 852
Calomel, crystalline, 1524
Calvo, Arturo, obituary, 130
Calyx phosphatic corn-flour, 1783
Camarri, Dr., salt and pellagra, 1195
Campbell, Dr. M., bilateral ovarian dermoid tumours, 1433
Cambridge, University of, 200, 338, 401, 623, 771, 1401, 1535, 1630, 1748; appointments and grants, 1616; graduation, 262, 1254, 1470, 1820; lectureship in hygiene established, 200; School of Medicine, examination results, 62
Cameron, Sir H. C., On the Evolution of Wound Treatment during the Last Forty Years (review), 1577
Cameron, Dr. S. J. M., some pathological considerations of extra uterine pregnancy, 53
Cammidge, Dr. P. J., detection of acetone in urine, 911
Campbell, Dr. C., the treatment of neuralgia, 233; and Masson, Dr., Intra-tracheal injections of izal in bronchiolectasis, 1353
Campbell, Dr. H., disappearance of the subcutaneous fat above the region of the lower extremities, 835; rôle of the blood plasma in disease, 313, 375, 538, 754, 827, 953
Campbell, Dr. H. J., Banti's disease treated by x rays, 290
Campbell, Mr. J. A., on the opsonic index, 455

CANADA, CORRESPONDENCE FROM.—Changing the medical law in the province of Quebec, 619—Cremation in Montreal, 1261—Death of Dr. William Henry Drummond, Montreal, 1251; Dr. G. A. Cape Town, plague in, 1446
Caprera, "Civic Hospital" at, 1827
Carmichael (Dr. E. W. S.), acute general peritonitis, operation for, case exhibited (Mongolian idiot), 1432
Cantlie, Mr. J., the currant as a food, 482
Capital punishment, abolition of, homicide in Italy in relation to, 1195
Carbolic acid co-efficient (see Rideal-Walker co-efficient)
Carbon tetrachloride, liquid consisting of, used for dry shampooing and causing dangerous symptoms (Dr. H. O. Colman and Dr. C. H. Marshall), 1709
Carcinoma of breast, specimen, 434; and cirrhosis of liver, 733; (early) of the cervix uteri treated by abdominal hysterectomy and pelvic dissection, 810; of cervix uteri, pathology of, 890; of jejunum, operation for, 293; of ovary, specimen, 810; of pylorus, gastro-jejunostomy for, 812; primary, of urethra, 1694; resection of jejunum and colon for, 535; treatment by x rays, 211
Cardiac hypertrophy, operative treatment of, 325; tonic, calcium salts as (Mr. J. Stark), 1710
Cardio-vascular affections in hereditary syphilis, 1673
Cardiff, administration of Midwives Act at, 1744; foreign lunatics in, 392; health report of, 549; Hospital Sunday in, 1211; housing conference at, 392; infantile mortality at, 839; infirmary needs of, 1255; meat inspection by police at, 1255; meeting of British Dental Association at, 1459; milk-supply of, 391, 1444; adulteration, 127, 195; police-surgeons, 1611; port sanitary authority, 1324; provision of dinners for under-fed school children, 692; report of medical officer of health, 1390; scarlet fever at (milk-borne), 1676; unqualified practice of dentistry in, 1393
Cardiff Infirmary, 549, 839, 1579; annual meeting of governors, 691
Carducci, Giosuè, last illness of, 512
Cargill, Mr. L. V., and Mayou, Mr. M. S., case of a flat sarcoma of the choroid, 23
Carlsbad, treatment at, for urinary diseases (Dr. Oscar Kraus), 1222
Carlyle, Thomas, The French Revolution (World's Classics, vols. cxxv., cxxvi.), (review), 1328
Carmarthen Asylum, 1576
Carmichael, Mr. E. W. S., child whose cæcum and ascending colon had been resected 16 months previously for tuberculous stricture, 94; and Wade, Dr. Henry, a case of primary sarcoma of the liver in a child aged four months, 1227
Carmichael prize essay, 1730
Carnegie Trust: reform required in Scotch universities, 467
Carnarvonshire, quarries of, accidents in, question regarding, in Parliament, 1129
Carotid artery, common, ligature of, pulsating exophthalmos treated by, 515

Carpenter, Dr. G., œdema in an infant, 295; rearing of children, 596; nephritis in infants, 811
Carpets (filthy) used for bed stuffing, 1241
Carr, Dr. J. W., use of alcoholic beverage, 1111
Carroll, Lieutenant and Assistant Surgeon James, appointed to rank of major, 981
Carter, Dr. Alfred H., appointed magistrate, 937; resignation of his hospital appointments, 393
Carter, Mr. R. Brudenell, on eugenics and descent, 960
Carter, Dr. W., variations in the normal temperature, 807; rôle of mercury in modern therapeutics, 1035
Carvellhier, Prof., treatment of phthisis by smoking belladonna (Looking Back), 237
Cary, Mr. A. J., presentation to, 1331
Case Teaching in Medicine (Dr. R. C. Cabot) (review), 1435
Castellani, Dr. A., paratyphoid fever in the tropics: cases of mixed infection, 284
Castle Bromwich, health report of, 549
Cat, experimental excision of portions of kidneys, results, 226; eye of, adhesion of persistent pupillary membrane to cornea in, 23
Cataphoresis, cocaine, induction of local anæsthesia by, 900
Cataract, extraction of, suppuration in wound after, 650; 130 consecutive operations without a failure (Mr. C. Higgens), 1003; eye protection for use after, 1170 (see also After-cataract)
Catarrh (see also Colds in the head)
Catgut, iodised, used in suture of uterine wall after Cæsarean section, 27; ligatures and buried sutures with special reference to (Mr. A. E. Johnson), 1074
Cathartic compound, 1783
Cathcart, Mr. C. W., exhibition of patient after removal of the Gasserian ganglion for epileptiform neuralgia, 93; use of massage and movement in the treatment of fractures, 1712
Cathcart, Dr. G. C., fibroma of larynx, 233
Catheterisation sheath, aseptic ureteral, 1233
Catheters, gum-elastic, sterilisation by formalin vapour, 509
Cattle, Dr., exhibition of specimen of mediastinal tumour, 25; exhibition of case of mediastinal tumour, 25
Cattle, Dr. C. H., some remarks on typhoid fever, 434
Cattle, tuberculous, compensation to butchers for slaughter of, 978
Cattley, Dr. R., the localisation of potassium in malignant tumours, 13
Caussade, M., and Joltrain, M., amœbic dysentery originating in Paris, 694
Cautley, Dr. E., girl, aged nine, with diabetes insipidus, 295; case of cerebral tumour, 590; huge inguinal hernia in conjunction with basal meningitis, 590; abdominal tumour, 859; cerebro-spinal meningitis, 1779
Cavendish lecture on the conservative surgery of the abdomen (Mr. C. R. B. Keetley), 1761
Cellulitis and myositis of abdominal wall simulating intra-abdominal disease, 951; of spermatic cord (Mr. F. C. Madden), 505
Centenarians, deaths of, 212, 401, 698, 741, 1127, 1749
Centenary of Operateurinstitute (Vienna), 981
Central London Ophthalmic Hospital (Gray's Inn-road), improvements at, 263
Central Midwives Board, 475, 697, 769, 1197, 1465, 1629; correction of mis-statement, 612
Centrifuge, water-driven, demonstration on, 226
Cerebellar-pontine cyst, 1653
Cerebellum, abscess of, following otitis media, 1229; specimen exhibited, 1020, 1021 (see Ataxy, cerebellar)
Cerebos salt, 745
Cerebro-spinal fluid, diagnostic and therapeutic significance of, 1365, syphilis antitoxin in, 618; meningitis (see Meningitis, cerebro-spinal)
Cerebrum (see Brain)
"Certificat d'études, médicales supérieures," annulled, 842
Certificate of exemption from, and conscientious objector to, vaccination (leading article), 593
Certificates under Workmen's Compensation Act, 1265
Cerumen, removal of, from external auditory canal, 340
Cervical canal, fibroid polypus of, 233; region, myelopathic trichosis of, 1492
Cervix, advisability of removal in performing hysterectomy, 1018; carcinoma (early) of, treated by abdominal hysterectomy and pelvic dissection, 810; pathology of, 890; fibroid tumour of, 1021; tumour of, removed by abdominal hysterectomy, clinical and anatomical study, 511; single condyloma of, 811; of uterus, cancer in, 856
Cette, oysters from, causing epidemic of typhoid fever, 551
Chalfont colony for epileptics, 310
Chalmer's Hospital (Edinburgh) annual report of, 258
Chambers, Dr. Helen, note on a case of rupture of the root of the lung without injury to the chest wall, 22
Chance, Sir William, Bart., Vagrancy, being a review of the Report of the Departmental Committee on Vagrancy (1906) (review), 32
Chancre, primary, in nostril (Mr. A. Baldwin), 287
Chantemesse, M., an auxiliary treatment in intestinal perforation, 1815
Chapin, Dr. L. D., intrapleural injections of formalin in recurrent pleural effusion, 1811
Chapman, Dr. C. W., two cases of aneurysm of the aorta, 1017
Charcoal biscuits, 441
Charcot's disease of right shoulder, 813
Charities, local (Birmingham district), bequests to, 391; London, Royal Guide to (Herbert Fry) (review), 595
Charity Maternity Hospital, Paris, rearing of premature children at, 1747
Charity organisation societies, conference of, 1471
Charteris, Dr. F. J., on heart block, 26
Chatin, M., and Desmoulières, M., sulphur waters and mercurial treatment, 1747
Cheatle, Mr. A., The Surgical Anatomy of the Temporal Bone from Birth to Adult Life (review), 814; exhibition of series of 96 temporal bones showing infantile condition, 1364
Cheek, right, small nodule upon, 298
Cheese, poisoning by (Looking Back), 904, 1031

Digitalis, physiological action of, 1452

Dimmock, Dr. A. F., demonstration of the uric meter, 364; and Branson, Mr. F. W., some new methods for the determination of uric acid, including a simple clinical process, 14

Dinners, complimentary, to Dr. W. Bruce, 196; to Dr. J. M. Beattie, 1745; *to* Principal Donald MacAlister, 1631; *to* Mr. *Pietro* Michelli, C.M.G., 247, 553; to Dr. R. A. Stawell (Melbourne), 621; to Dr. Norman Walker, 128

Dinners, various: Apothecaries' Hall of Ireland, 550; Association of Scottish Medical Diplomates, 435; British Gynaecological Society, 135, 262; British Home for Incurables, 1556; Glasgow University Club, 1617; Hunterian Society, 523; Maccabaeans, 1471; Medical Society of London, 771, 450; Medico-Legal Society, 1617; Middlesex Hospital, 1242, 1365; National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis, 1375; National Hospital for Paralysed and Epileptic, 773; Odontological Society of Great Britain, 401; Queen's College, Belfast, 841; Royal College of Physicians in Ireland, 1395; Royal College of Surgeons of England, Hunterian festival, 522; Royal College of Surgeons in Ireland, 331; Royal Medical Society, Edinburgh, 458; Royal Sanitary Institute, 1290; Scottish Volunteer medical officers, 1450; Volunteer Ambulance School of Instruction, 1023; Welsh medical, 1565; West London Post-Graduate College, 1372

Diphtheria at Birmingham, 126, 858; at Chipping Sodbury, 127; at Hatton, 549; outbreaks in Ireland, 969; prosecution for exposure of patient suffering from, in cab, 1540; at Tiverton, 1551; control of infection, 295; prognosis of, 741; treatment of, 741; by antitoxin, results, 1395; antiserum, quantitative relationship between globulin and antitoxin of, 225; laryngeal, intubation of larynx in, 1290; toxin of, standardisation of, in relation to normal variations in weight of guinea-pig, 225. (See also Diphtheritic membrane). (See also Pseudo-diphtheria bacillus)

Diphtheritic membrane involving pharynx, oesophagus, and respiratory passages (Dr. F. L. Field), 151

Diplococcus intracellularis (see Meningococcus)

Diplopia, vertical, case, 93

Directories, City of London (review), 1731; (see Medical Directory)

Directory (Classified) of Metropolitan Charities (review), 595

Disclaimers of unauthorised publicity in lay journals, 774, 1259

Disease, inebriate reformatories for, 177; Prevention of (War with Disease) (review) (Dr. F. MacCabe), 825; in relation to hospitals, 107; physiological effects of high frequency currents in (Dr. S. Sloan), 1327, 1205; prophylaxis of, correction of misstatement in lay press, 1775; rôle of blood platelets in (Dr. H. Campbell), 313, 375, 535, 454, 827, 963, 1093; transmission of, and marriage (Parliamentary question), 1233

Diseases, general, relation of diseases of ear, nose, and throat to, 671; Internal, Prophylaxis and Treatment (Dr. F. Forchheimer) (review), 1165; (See also Industrial

Disinfectants, electrolytic, manufacture of, at Poplar, 922; okol, 441; standardisation of, 108; questions regarding, in Parliament, 819, 1519

Disinfection of books and garments, new regulations for, 845

Dislocation (habitual) of patella (? congenital), 1266; of hip-joint, congenital, treatment, post operative (Mr. J. Jackson Clarke), 659; hip, double congenital, treatment by Lorenz's method successful, 1021; of knee (complete outward), 157; of metatarsus outwardly and of first cuneiform bone, 979; of semilunar bone complicating fracture of styloid process of radius (Mr. P. R. Wrigley), 658; of shoulder, 295; subspinous, of head of left humerus, 1364; of thumb, reduction of, 1505

Dislocations: Atlas und Grundriss der traumatischen Frakturen und Luxationen (Prof. H. Helferich) (review), 743

Dispensaries, Hospital Sunday Fund award and out-patients' visits (1906), 1548

Dispensary, gratuitous, for tuberculous patients in Constantinople, 846; doctors in Ireland, question regarding, in Parliament, 1767

Dispensers, certificated, association of, 772

Dissections, Illustrated (Mr. C. G. Brodie) (review), 815

Distemper in dogs, committee on, 1790

District nursing association, Leeds, 691

Diuretics, theobromine class of, 602

Diverticulum, congenital, *of the stomach and* duodenum in a physiological hour-glass stomach, 1296

Divine, Dr. Thomas, sanitary condition in relation to infantile mortality, 358

Dixon, Dr. A. F., exhibition of specimens and x ray photographs of upper end of femur to illustrate arrangement of cancellous lamellae and of calcar femorale, 509

Dobie, Dr. D. Robertson, method of delivery by forceps in some difficult occipito-posterior cases, 512

Dobson, Mr. J. F., case of spinal caries, 1761

Dobson, Mr. J. F., and Jamieson, Mr. J. K., lymphatic system of the stomach, 1061; lectures on lymphatic system of the caecum and appendix, 1137

Dobson, Dr. Margaret, tuberose sclerosis of the brain, 193

Dockyards, royal, lead poisoning in, *question* regarding, in Parliament, 1129, 1257

Dodd, Mr. F. Lawson, "Socialism and the medical profession," 1243

Doctors and Patients (Dr. J. Johnston) (review), 1721

Dodd, Mr. J. T., election of guardians, 755; two practical points in Midwives Act (1902), 823

Dodds, Dr. B., the use of alcoholic beverages, 1187

Dog, goitre in, case of, 552

Dogs, dangerous, legal decisions regarding, 1035; distemper in, committee on, 1790; (Injuries to Persons) Bill, 927

Dolgelly, health report of, 549

Domecq's brandy, 33

Donald, Dr. Archibald, chronic septic infection *of the uterus and its appendages*, 91; ectopic pregnancy co-existing with uterine pregnancy, 512

Donald, Mr. Robert, the Municipal Year-Book of the United Kingdom *for* 1907 (review), 1024

Donations and bequests, 135, 193, 261, 326, 401, 474, 517, 623, 693, 847, 961, 1127, 1193, 1264, 1332, 1535; *to Guy's Hospital*, 624; to Paisley Infirmary, 1814; Royal United Hospital, Bath, 1333, 1749

Donelan, Dr. J., patient with destruction of columella of nose exhibited, 1165; frequency of marked enlargement of the pharyngeal extremities of the Eustachian tubes, 1361

Donnelly, Dr. T., report of the Viceregal Commission on the Poor-law, 591

Donnelly, Deputy Surgeon-General Sir John McNeale, obituary, 622

Doyen, M., and Vaillard, M., antidysenteric serum, 1121

Doran, Mr. A. H. G., after history of a case of fibroid of broad ligament associated with an ovarian cyst, 735; malignant vaginal polypus secondary to an adrenal tumour of kidney, 1037

Dore, Dr. S. E., case of bullous disease (shown *for Dr. Pringle*), 295

Douglas, Dr. Carstairs C., idiopathic steatorrhoea, 537; The Laws of Health, a Handbook on School Hygiene (review), 1721; pancreatic reaction of the urine and other associated means of diagnosing disease of the pancreas, [illegible]

Douglas, Mr. J. S. C., a case of influenzal meningitis, 85

Cope, Dr. V. Z., and Lees, Dr. D. B., two cases of pulmonary regurgitation, 1424
Copeman, Dr. A. H., the use of alcoholic beverages, 973
Copeman, Dr. S. Monckton, and Hake, Dr W., the presence of hydrochloric acid in the stomachs of mice inoculated with cancer, 226

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Diagnosis of mediastinal tumours, 24—Measles: its mortality, complications, and sequelæ, 25—Treatment of prostatic congestion by electrical methods; Extensive ulceration of rectum, 95—*Diagnosis and treatment* of some diseases of the skin; Specimen of true papilloma of bladder; Uterus with contained fœtus and placenta, 232—Carcinoma of breast, case; Ovarian dermoid cyst; Some remarks on typhoid fever; X rays and operation in treatment of sarcoma of pharynx, case, 434—Chronic hoarseness, 652—Abdominal cases difficult to diagnose, 740—Chronic suppurative otitis media; X rays in diagnosis of renal calculus, 948—Treatment of diabetes; Exhibition of specimens, 1087—Cases of pneumothorax, 1163

OBSTETRICAL SOCIETY OF LONDON.—Chronic metritis, 91—Election of officers; Exhibition of specimens, 429—Presidential address; After-history of a case of fibroid of broad ligament associated with an ovarian cyst; Perithelioma of uterus, 735—Exhibition of specimens, 738—Advisability of removing the cervix in performing hysterectomy; Exhibition of specimens, 1018—Malignant vaginal polypus secondary to an adrenal tumour of kidney; Intra-peritoneal rupture of bladder occurring during labour, 1297—Pregnancy in a rudimentary uterine horn; Primary vaginal embolic chorion-epithelioma; Chorion-epithelioma complicated by hæmatometra; Exhibition of specimens, 1652

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Papillary membrane; Sarcoma of choroid; Total avulsion of iris, with retention of vision, 23—Exhibition of cases; Stereoscopic vision; Streptococcic infection of conjunctiva; Family tree of nyctalopia; Tubercle filling eyeball in which opsonic index was regularly taken, 429—*Exhibition of cases and specimens*; Paralysis of vertical movements of both eyes; Foreign body in right eye; *Polycoria associated with chronic glaucoma*, 883—Sympathetic irritation after injury to other eye; Cysts of pars ciliaris retinæ; Exhibition of cases and *specimens*; Thrombosis of cavernous sinus in meningitis, 885—Lantern demonstration; Colour vision; Syphilitic affection of the eye; *Rupture of* the pectinate ligament; After-cataract; Perinaud's conjunctivitis; Telangiectasis of retinal vessels, Exhibition of *specimens*, 1573—Congenital night blindness; Sub-retinal cysticercus; Metastatic tumour of choroid, 1711

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Exhibition of cases, 1364

PATHOLOGICAL SOCIETY OF LONDON.—Observations on MacConkey's bile salt neutral red medium; Typhoid fever diagnosed by blood culture in the absence of agglutination reaction, A third case of influenzal endocarditis diagnosed by blood culture; The incidence of spontaneous cancer in mice; Observations on the treatment of lesions by passive congestion; Method for testing the digestive power of the white corpuscle, 157—Laboratory meeting at the Lister Institute; Quantitative relation between the globulin and the antitoxin of diphtheria anti-serum, 225—The parathyroid glands in man: a histological study of the human parathyroid glands, 687—Two cases of cystinuria with excretion of diamines; Excretion of creatinin in pseudo-hypertrophic muscular dystrophy; *A case of sulph-hæmoglobinæmia*; Apparatus for estimating electric conductivity of small quantities of liquids; New case of alkaptonuria, 659—Antityphoid inoculation in the army; Observations on the spirochætæ of relapsing fever and tick fever; Note on blackwater fever in Sierra Leone; Pseudo-diphtheria bacillus from a case of middle-ear disease; Bacillus typhosus from periosteal abscess *one* year after typhoid fever, 876, 877—Exhibition of specimens; Inoculated syphilis in chimpanzee; Morbid histology of the suprarenal glands, 1293—Hæmogregarines in snakes; Histogenesis of goitre; Osteolipoma of the brain; Valedictory address, 1650

PATHOLOGICAL SOCIETY OF MANCHESTER.—Discussion on opsonins, 27—Cystine calculi; Lesions of cranial nerves in general paralysis of insane and those produced experimentally; Obstruction of peri-glandular vessels of nasal mucous membrane, 663—Exhibition of specimens, 890, 1298—Pathogenic invasion in intracranial sepsis secondary to suppurative middle ear disease, 1298—Exhibition of cases, 1575

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Our debt to Ireland in the study of the circulation, 25—New form of pessary; Uterus affected with cancer of both cervix and fundus; Ovarian cyst; Vesical calculus with nucleus consisting of pedicle silk; Case of labour obstruction by *fibroid tumour*, 94—Exhibition of specimens, 293, 737—Treatment of gastric ulcer, 362—Musculature of the *villi*; *Estimation* of urea and hydroxybutyric acid in urine; Exhibition of specimens; *Exhibition of apparatus* for sterilising ureteral or other form of gum-elastic catheters by means of formalin vapour; *Contribution to technique of operations* on the appendages, 509—Frontal sinusitis, 738—Maniacal chorea; Moveable spleen, 809—Exhibition of specimens; Pubiotomy (hebotomy), 886, 887—Exhibition of specimens; Sacro-coccygeal tumour; Cerebro-spinal meningitis, 1020, 1021—Exhibition of cases and specimens; Addison's *disease*; *Cerebro-spinal fever*, 1160—Exhibition of instruments; Eclampsia; Bier's hyperæmia in gynæcology; Report of the Rotunda Hospital, 1227—The State and syphilis, 1228—Lympho-sarcoma of lung; *Tuberculin treatment of tuberculosis*; Spleno medullary leukæmia; Cerebellar *pontine cyst*, 1652—Exhibition of specimens; *Discussion on* the report of the Rotunda Hospital, 1653

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Demonstration on the spirochæta *pallida*; Note on the pathology of syphilis; Observations on Cheyne-Stokes respiration, 91—Idiopathic cyanosis due to sulph-hæmoglobinæmia, 225—*Ligation of the renal* vessels for the cure of persistent urinary renal fistula, with one successful case; Case of cervical myelopathic trichosis, 1492—On the de novo origin of bacteria, bacilli, vibriones, micrococci, torulæ, and moulds in certain previously superheated saline solutions contained within hermetically sealed tubes, 225—*Condition of the blood-vessels* during shock, 607—Fractures of the odontoid process of the axis, 1351—Human and bovine *tuberculosis, with especial reference to* treatment by special kinds of tuberculin, 684—Observations on a case of chyluria occurring in England, with a report of the post-mortem examination, 733—*Early* diagnosis and cure of pre-suppurative stage of amœbic hepatitis; Common sporadic seven-day fever of *Indian* ports, simulating dengue, 1016, 1017—*Diagnosis* of Addison's disease, 1158—Co-existence of appendicitis and obstruction; Dislocations and fractures of the thumb and great toe; Volvulus of the entire small intestine, cæcum, and ascending colon, 947

SOCIETY OF ANÆSTHETISTS.—Poisonous after effects of chloroform and ether, 433—Use of ethyl-chloride, 740

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—Discussion on rickets, 24—Exhibition of cases and specimens, 295, 590, 829, 1163, 1365 Protection of rheumatic *children*; *Volvulus of* small intestine round caseous mesenteric gland, 294—Tuberculosis of testis *in infants*, 823—Pneumonia in children, 1574—*Acute rheumatism* in children; Cerebro-spinal meningitis; Contraction of the *tendo Achillis*; *Bilharzia*; Œdema of the limbus, 1779

SOUTH-WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Diagnosis and treatment of malignant disease of the cæcum, 170

SOUTH WEST LONDON MEDICAL SOCIETY.—Some common deformities of children, 592—Constipation and dilatation of the colon, 812—Exhibition of cases, 1057—Early differential diagnosis of abdominal pain, 1057—Cerebro-spinal fluid, 1355

THERAPEUTICAL SOCIETY.—Short notes on a method for rendering creosote and cannabis indica soluble and some little known medicinal remedies, 293—Control of supernormal arterial pressure, 1165

ULSTER MEDICAL SOCIETY.—Cerebro-spinal meningitis *in Belfast*, 587—Examination of the urethra and bladder by electric light, 733

Medical officers and the Workmen's Compensation Act, 1442; in crofting counties, question regarding in Parliament, 699; of friendly societies, remuneration of, 337; of Scottish Highlands and Islands, 1116; of sick clubs, 618 (see also Poor law medical officers)
Medical Officers, parochial, Bill (Scotland), 1127
Medical organisation in Hungary, 1047
Medical posts at His Majesty's Embassies (Parliamentary question), 1683
Medical Practice, the Prohibition of, by Companies Bill, 1822
Medical practice: openings for, fee demanded for introduction to, 923; openings for, etiquette with regard to, 990; openings for, propriety of advertising, 629; propriety of replying to advertisements for, 701; prohibition of, by companies, Bill to abolish, 848
Medical practitioners: action in relation to Midwives Act, 976; unqualified, and quack medicines, legal position in Vienna, 1528
Medical profession as affected by alterations in income tax under recent Budget, 1176
Medical profession and compulsory military service, 610, 764
Medical profession and hospital funds, 323
Medical profession and French income-tax, 1746
Medical profession, benevolent agencies of (leading article), 99, 461
Medical profession, hospital funds in relation to (leading article), 238
Medical profession in Austria, 695
Medical profession in Germany, obstructions to practice abroad, 233
Medical profession, organisation of, in France, 911, 1190
Medical profession, outlook of, scientific, social, financial (Dr. J. Grey Glover), 1135, 1177
Medical profession, state of (Looking Back), 1732
Medical profession, statistics of advertisements sent to, by post, 329
Medical Protection Society (see London and Counties Medical Protection Society)
Medical purposes, suggestion of duty-free alcohol for, 40
Medical qualifications in France, admission of foreigners to, 651
Medical referees, position of, under new Workmen's Compensation Act, 860
Medical referees, proposal for association of, 1114; women as (Parliamentary question), 1750
Medical Register, restoration of name to, resolved by General Medical Council, 1510
Medical relief for infants, question regarding, in Parliament, 698
Medical schools, instruction of medical economics in, 336; report on, in United States, 1615
Medical schools, teaching of public health in (leading article), 239
Medical science, state of, in Scotland at time of Reformation and at time of Union (1707), 364
Medical sciences (see Institute of Medical Sciences)
Medical service of the Nile reservoir works, 1444
Medical service of Royal Navy, slights put upon, 1457
Medical Service, West African, 120
Medical Sickness, Annuity, and Life Assurance Friendly Society, general meeting and annual report, 1538
Medical Society of Victoria, amalgamated with Victorian branch of British Medical Association, 620
Medical students, London, of average ability, means of obtaining degree in medicine by, 1384
Medical study, early, concentration of, supported by Medical School of St. Thomas's Hospital, 1737
Medical supplies for Irish guardians (Parliamentary question), 1333
Medical term in Quebec and McGill University, 1122

MEDICAL SOCIETIES.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—Myasthenia Gravis; treatment of acute otitis media, 589

ÆSCULAPIAN SOCIETY.—Exhibition of pathological specimens, 95—Common surgical affections frequently met with in out-patients, 233—Significance of paralysis of cranial nerves, 353—Exhibition of cases, 512—Diseases of the ear, nose, and throat in relation to general diseases, 661—Treatment of tuberculous disease of the knee, 813—Demonstration of eye cases, 1021—Hypertrophy of the heart, 1162

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens; Alcohol with special reference to its therapeutic value and nutritional uses, 512; Reflections of an old microscopist, 663—Study of post-typhoid pyrexia, 1779

BRADFORD MEDICO-CHIRURGICAL SOCIETY AND BRADFORD DIVISION OF THE BRITISH MEDICAL ASSOCIATION (Joint meeting).—Some remarks on forceps delivery, 1088

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases, 592—Exhibition of cases; lymphatic leukæmia; Royal Commission on tuberculosis, 1229—Annual meeting, 1654

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—Treatment of gout by ingestion of common salt-containing waters, 25—Influence of climate on gout and rheumatism, 434—Present position of treatment of tuberculosis of marine climates, 887, 1164

BRITISH GYNÆCOLOGICAL SOCIETY.—Exhibition of specimens, 512—Exhibition of cases; Mobile kidney; Anterior nephropexy, 810—Exhibition of specimen of extra-uterine pregnancy; Radical cure of prolapse of uterus; Ruptured ovarian cyst, 1087—Surgical treatment of inflammatory diseases of the uterine appendages, 1365

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—Chronic suppuration of middle ear, exhibition of cases, 231—Exhibition of cases, 812, 1653—Fatal case of otitic cerebral abscess and meningitis, 1654

BURNLEY AND DISTRICT MEDICO-ETHICAL ASSOCIATION.—Four tumours of ectopic gestation, 296

CAMBRIDGE MEDICAL SOCIETY.—Voluntary notification of pulmonary tuberculosis, 736

CHELSEA CLINICAL SOCIETY.—Some pathological aspects of old age, 26—Suppurative disease of the middle ear, 662—Some of the factors that contribute to success in abdominal operations; Treatment of apoplexy, 1161

CLINICAL SOCIETY OF LONDON.—Acute pneumonia with abscess of the lung and acute endocarditis; Myxœdema with changes in the parathyroid glands; The connexion of tetany with dilated colon in children, 169—Idiopathic dilatation of colon; Paralysis, general, of insane; Typhoid fever with complications, 426—Spinal meningocele treated by operation after rupture; Resection of the jejunum and colon for carcinoma; A new method of excision of joints, 586—Medical and surgical treatment of congenital pyloric stenosis, 725, 734—Clinical evening; exhibition of cases, 292, 884, 885—Method of applying silver wire filigrees for cure of inguinal hernia; Acute solitary suppuration in psoas and iliacus muscles; Value of anti-colon bacillus serum, 1084—Prolonged intermittent pyrexia; partial heart block; foreign bodies in the bronchi; annual meeting, 1493—Exhibition of cases, 1226—Gastro-enterostomy for chronic ulcer; Persistence of Widal's reaction after typhoid fever; Precocious obesity and hirsuties with hypernephroma, 1362, 1363

CLINICAL SOCIETY OF MANCHESTER.—Treatment of enteric fever, 662

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Annual meeting, 1535—Exhibition of cases, 298—Exhibition of cases; Actinomycoses, 741—Exhibition of cases, 946, 1229

DERMATOLOGICAL SOCIETY OF LONDON.—Exhibition of cases, 296, 1164, 1165

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—Fibroid uterus; Suppurative diseases of the ear, 363—Aortic aneurysm, 741—Hair affected with microsporon Audouini, 741—Spontaneous fracture of femur, 741—Gastric tetany, 1088—Exhibition of cases, 1494

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Loss of stereognostic sense; Notification of infectious diseases; Some cases treated by Bier's method; Some improvements in cutaneous therapeutics, 229—Meningococcal cerebro-spinal meningitis; treatment of some diseases commonly regarded as of gouty origin, 430—Exhibition of patients, 93—Electrical conductivity of the blood and urine in health and disease and as a test of the functional efficiency of the kidney, 229—Prognosis and treatment of lobar pneumonia; Use of the opsonic index in the diagnosis of tuberculosis, 808—Exhibition of cases, 1431—Differentiation of the varieties of extra-systole, 1297—Intubation of larynx in laryngeal diphtheria, 1293—Exhibition of specimens; Administration of gas and ethyl chloride, Massage and movement in the treatment of fractures; The naso-pharynx as infection carrier in epidemic cerebro-spinal meningitis, 1711

EDINBURGH OBSTETRICAL SOCIETY.—Complications of pregnancy, 24—Acute albuminuria; Intractable uterine hæmorrhage and arterio-sclerosis of the uterine vessels, 169—Clinical and anatomical study of 30 cervical fibroids removed by abdominal hysterectomy; Method of delivery by forceps in some difficult occipito-posterior cases; Hysterectomy for pregnancy in uterine fibroid, 511, 512—Exophthalmic goitre in its relation to gynæcology and obstetrics; Lesions of the bladder, 812—Bilateral ovarian dermoid tumours, 1433—Status epilepticus, 1432—Vaginal Cæsarean section; Congenital goitre after administration of potassium iodide to the mother, 1713

EPIDEMIOLOGICAL SOCIETY.—Real and apparent differences in the incidence of cancer, 227—Ship beri-beri; Etiology of scurvy, 1574

FORFARSHIRE MEDICAL ASSOCIATION.—Cases of beri-beri; Clinical aspects of lymphosarcoma in children; Obstetric albuminuria and eclampsia; Subcutaneous emphysema complicating whooping-cough; Exhibition of cases, 511—Exhibition of specimens and instruments; Pulsus bisferiens, 738—Application of midwifery forceps; Cerebro-spinal meningitis, 739—Exhibition of patients; Water-borne enteric fever in Noran Valley; Uses and limitations of argyrol in ophthalmic practice; action of digalen on circulation, 1086, 1087

GERMAN BALNEOLOGICAL SOCIETY.—Annual meeting of, 1194

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—Heart block; Ectropion of lower lids of both eyes; Pancreatic reaction of urine; Prevalent diseases in Morocco, 26—A case of metastatic ophthalmitis; Ossiculectomy; Two cases of birth injury of the cornea; Treatment of neurasthenia, 232—Right recurrent laryngeal paralysis, 233—Opsonic index, 435—Histological diagnosis of the endotheliomata and their bearing on modern research work in cancer, 661—Sarcoma of the nose, 813—Ulcerative perforation of stomach; Ulcerative perforation of duodenum; Successful operations; Bier's treatment for infective lesions, 948—Skin-grafting; Traumatic asphyxia, 1164—Notes of a case of cerebellar abscess following otitis media; Notes on the condition of retro-bulbar neuritis; Empyema of the mastoid cells, 1229—Exhibition of cases; Primary cancer of the bronchus, relationship of myopia to school work, 1364

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—President's inaugural address; Exhibition of cases, 364—Exhibition of cases; Fibroid of cervix uteri; Pruritus vulvæ, 1021

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—Perforated peptic ulcer of the jejunum, 231—Fibromyoma of the ovary; Rupture of vagina with protrusion of bowel, 232—Lymphadenoma, 889

GLASGOW SOUTHERN MEDICAL SOCIETY.—Bacteriology of conjunctivitis, 364—Physio-psychology of hallucinations, 662

HARVEIAN SOCIETY OF LONDON.—Exhibition of cases, 295—Fatal extravasation of urine, psychorhythm and recurrent psychoses, 692—Diagnosis and treatment of fractures in neighbourhood of joints, 890—Ulcerative colitis, functional nervous disorders in childhood, 1227

HUNTERIAN SOCIETY.—Points in the diagnosis and treatment of duodenal ulcer, 363—Acetonuria, clinical significance and treatment, 511—Nephritis in infants; Administration of salicylates; Intussusception, 811—Exhibition of cases, 1021

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Presidential address on diphtheria and small-pox, 295—Discussion on reduction of infantile mortality without municipal milk depôts, 510—Inspection of food at our ports, 1164

LARYNGOLOGICAL SOCIETY OF LONDON.—Exhibition of cases, 29, 233, 1162, 1163

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Demonstration of uric meter; Exhibition of cases, 364—Exhibition of cases; Actinomycosis; Remarks upon the treatment of acute appendicitis, 591—Post-operative pneumonia and bronchitis; Surgical treatment of diseases of the nasal accessory cavities; *Exhibition* of cases and specimens, 947, 948—Exhibition of cases, 1161—Exhibition of specimens, 1433—Notes on Cerebro-spinal fever, 1433

LIVERPOOL MEDICAL INSTITUTION.—*Exhibition of specimens*, 25—*Duodenal ulcer*; Operations during typhoid fever; Lymphatic leukæmia; Forgotten medical worthies, 92—Acute hæmorrhagic pancreatitis (three cases with operation); Etiology of inguinal and femoral hernia; Ventrofixation of uterus, 227—New refractometer; Syphilis of the lung; The surgical treatment of focal epilepsy, 362—*Gametoid theory of cancer*, 430—Submucous resection of the nasal septum, pulsating exophthalmos, ligation of the common carotid artery, housing of the working classes in Liverpool, 558—Cleido-cranial dysostosis of Marie and Sainton; Recurrent paralysis of ocular muscles; Suppuration of the wound after cataract extraction; Malaria, 663—Pulmonary thrombosis and embolism; Epidemic *cerebro-spinal meningitis*, 740—Nephrectomy for renal sarcoma in children; Plexiform neuroma; Variations in the normal temperature; New astigmometer; Surgery *of* warfare and catastrophe, 807—Exhibition of cases; Treatment of the acute pathogenic infections with vaccines and sera, 885, 886—Benign cysts of the long bones; *Lymphatic leukæmia*; *Rôle of mercury in* modern therapeutics; Suppurative *cholecystitis*; Development *of* cerebral cortex, 1035—Suppurative otitis; Extroversion of intestinal *mucous membrane*; *Fracture of the* humerus; Empyema; Abnormal conditions within the chest wall, 1159—Nucleo-albuminuria simulating myelopathic albumosuria; Intra-tracheal injections of izal in bronchiolectasis; Epidemic cerebro-spinal meningitis; Renal and ureteral calculi and renal tumours, 1353

MANCHESTER CLINICAL SOCIETY.—Tuberculous skin affections, 1165—Congenital pyloric stenosis in infants; Acute infective bone disease unassociated with necrosis; Vesical calculus and methods in use for its removal, 610—Diagnosis of pulmonary tuberculosis *in its earlier stages*; *Carcinoma of the pylorus*, 811—Acute appendicitis, 1019

MANCHESTER PATHOLOGICAL SOCIETY.—Demonstrations at laboratory meeting, 233

MEDICAL SOCIETY OF LONDON.—Discussion on diagnosis and treatment of laryngeal cancer, 291—Exhibition of cases, 427—Operations for malignant growths of the naso-pharynx and pharynx; Hæmaturia due to bilharzia; Hæmatobia causing papillomata of the bladder, 555—Operative treatment of hepatic ascites, 853—Exhibition of cases, 1017—Surgical affections which simulate appendicitis; Cases of goitre removed under cocaine anæsthesia, 1143, 1159—General meeting; Mobility of the kidneys; Some heart affections without murmurs, 1361—Cause of the heart beat; Conversazione and annual oration, 1495

MEDICO-LEGAL SOCIETY.—Discussion on Midwives Act, 1902, 883—Papers on toxicology, 1165

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—Quarterly meeting 697

MIDLAND MEDICAL SOCIETY.—Exhibition of cases and specimens, 890, 1162—Exhibition of cases, 878, 879

NEWCASTLE-ON-TYNE CLINICAL SOCIETY.—Exhibition of cases, 593

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Exhibition of specimens, 27—Anterior vaginal hysterectomy; Ectopic gestation; Hypernephroma of left kidney; Uterus removed for cancer of cervix, 233—Exhibition of cases; Ectopic pregnancy coexisting with uterine pregnancy; Case of fatal vomiting, 512—Ruptured isthmial ectopic gestation; Uterine fibroid; Early carcinoma of the cervix uteri treated by abdominal hysterectomy and pelvic dissection; Modification in the technique of ventrofixation of the uterus, 817—Exhibition of cases; Treatment of albuminuria and eclampsia of pregnancy, 1193—Exhibition of specimens; Removal of large fibroid from uterus; Bilateral axial rotation of ovarian cysts during pregnancy; Tuberculous disease of uterus and appendages, 1160, 1161

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Address on the outlook of the medical profession, 1135

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Diagnosis of mediastinal tumours, 24—Measles: its mortality, complications, and sequelæ, 25—Treatment of prostatic congestion by electrical methods; Extensive ulceration of rectum, 95—Diagnosis and treatment *of some diseases of the skin*; *Specimen* of true papilloma of bladder; Uterus with contained fœtus and placenta, 232—Carcinoma of breast, case; Ovarian dermoid cyst; Some remarks on typhoid fever; *x rays and operation in treatment of sarcoma* of pharynx, case, 434—Chronic hoarseness, 662—Abdominal cases difficult to diagnose, 740—Chronic suppurative otitis media; X rays in diagnosis of renal calculus, 948—Treatment of diabetes; Exhibition of specimens, 1037—Cases of pneumothorax, 1163

OBSTETRICAL SOCIETY OF LONDON.—Chronic metritis, 91—Election of officers; Exhibition of specimens, 429—Presidential address; After-history of a case of fibroid of broad ligament associated with an ovarian cyst; Perithelioma of uterus, 735—Exhibition of specimens, 736—Advisability of removing the cervix in performing hysterectomy; Exhibition of specimens, 1018—Malignant vaginal polypus secondary to an adrenal tumour of kidney; Intra-peritoneal rupture of bladder occurring during labour, 1297—Pregnancy in a rudimentary uterine horn; Primary vaginal ectopic chorion-epithelioma; Chorion-epithelioma complicated by hæmatometra; Exhibition of specimens, 1652

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Papillary membrane; Sarcoma of choroid; Total avulsion of iris, with retention of vision, 23—Exhibition of cases; Stereoscopic vision; Streptococcic infection of conjunctiva; Family tree of nyctalopia; Tubercle filling eyeball in which *opsonic index* was regularly taken, 429—Exhibition of cases and specimens; Paralysis of vertical movements of both eyes; Foreign body in right eye; Polycoria associated with chronic glaucoma, 693—Sympathetic irritation after injury to other eye; Cysts of pars ciliaris retinæ; Exhibition of cases and specimens; Thrombosis of cavernous sinus in meningitis, 885—Lantern demonstration; *Colour* vision; Syphilitic affection of the eye; Rupture of the pectinate ligament; After-cataract; Parinaud's conjunctivitis; Telangiectasis of retinal vessels; Exhibition of specimens, 1573—*Congenital night blindness*; *Sub-retinal* cysticercus; Metastatic tumour of choroid, 1711

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Exhibition *of* cases, 1364

PATHOLOGICAL SOCIETY OF LONDON.—Observations on MacConkey's bile salt *neutral red* medium; Typhoid fever diagnosed by blood culture in the absence of agglutination reaction; A *third case of influenzal endocarditis* diagnosed by blood culture; The incidence of spontaneous cancer in mice; Observa*tions on the treatment of lesions* by passive congestion; Method for testing the digestive power of the white corpuscles, 157—Laboratory meeting at the Lister Institute; Quantitative relation between the globulin and the antitoxin *of* diphtheria anti-serum, 225—The parathyroid glands in man: a histological study of the human parathyroid glands, 557—Two cases of cystinuria with excretion of diamines; Excretion of creatinin in pseudo-hypertrophic muscular dys*trophy*; A case of sulph-hæmoglobinæmia; *Apparatus* for estimating electric conductivity of small quantities of liquids; *New case of* alkaptonuria, 659—Antityphoid *inoculation* in the army; Observations on the spirochætæ of relapsing fever and tick fever; Note on blackwater fever in Sierra Leone; Pseudo-diphtheria bacillus from a case of middle-ear disease; Bacillus typhosus from periosteal abscess one year after typhoid fever, 806, 807—Exhibition of specimens; Inoculated syphilis in chimpanzee; Morbid histology of the suprarenal glands, 1293—Hæmogregarines in snakes; Histogenesis of goitre; Osteoliposis of the brain; Valedictory address, 1650

PATHOLOGICAL SOCIETY OF MANCHESTER.—Discussion on opsonins, 27—Cystine calculi; Lesions of cranial nerves in general paralysis of insane and those produced experimentally; Obstruction of peri-glandular vessels of nasal mucous membrane, 663—Exhibition of specimens, 890, 1233—Pathogenic invasion in intracranial sepsis secondary to suppurative middle ear disease, 1293—Exhibition of cases, 1575

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Our debt to Ireland in the study of the circulation, 25—*New* form of pessary; Uterus affected with cancer of both cervix and fundus; Ovarian cyst; Vesical calculus with nucleus consisting of pedicle silk; Case of labour obstruction by fibroid tumour, 94—*Exhibition of specimens*, 293, 737—Treatment of gastric ulcer, 362—Musculature of the villi; Estimation of urea and hydroxybutyric acid in urine; Exhibition of specimens; Exhibition of apparatus for sterilising ureteral *or other form of gum*-elastic catheters by means of formalin vapour; Contribution *to* technique of operations *on the appendages*, 509—*Frontal* sinusitis, 738—Maniacal chorea; Moveable spleen, 809—Exhibition of specimens; Pubiotomy (hebotomy), 886, 887—Exhibition of specimens; Sacro-coccygeal tumour; Cerebro-spinal meningitis, 1020, 1021—Exhibition of cases and specimens; Addison's disease; Cerebro-spinal fever, 1160—Exhibition of instruments; Eclampsia; Bier's hyperæmia in gynæcology; Report of the *Rotunda Hospital*, 1227—The State and syphilis, *1228*—Lympho-sarcoma of lung; Tuberculin treatment of tuberculosis; Spleno-medullary leukæmia; Cerebellar pontine cyst, 1652—Exhibition of specimens; Discussion *on* the *report of* the Rotunda Hospital, 1653

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Demonstration on the spirochæta pallida; Note on the pathology of syphilis; Observations on Cheyne-Stokes respiration, 91—Idiopathic cyanosis due to sulph-hæmoglobinæmia, 225—Ligation of the renal vessels for the cure of persistent urinary renal fistula, with one successful case; Case of cervical myelopathic trichosis, 1492—On the de novo origin of bacteria, bacilli, vibriones, micrococci, torulæ, and moulds in certain previously superheated saline solutions contained within hermetically sealed tubes, 225—Condition of the *blood-vessels* during shock, 507—Fractures of the odontoid process of the axis, 1351—Human and bovine tuberculosis, with especial reference to treatment by special kinds of tuberculin, 534—Observations on a case of chyluria occurring in England, with a report of the post-mortem examination, 753—Early diagnosis and cure of *pre-suppurative* stage of amœbic hepatitis; Common sporadic seven-day fever of Indian ports, simulating dengue, *1016*, 1017—*Diagnosis* of Addison's disease, 1155—Co-existence of appendicitis and obstruction; Dislocations and *fractures of the* thumb and great toe; Volvulus of the entire small intestine, cæcum, and ascend*ing colon*, 947

SOCIETY OF ANÆSTHETISTS.—Poisonous after effects of chloroform and *ether*, 433—*Use of* ethyl-chloride, 740

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—Discussion on rickets, 24—Exhibition of cases and specimens, 295, 591, 889, 1163, 1365—*Protection of rheumatic* children; Volvulus of small intestine round caseous mesenteric gland, 294—Tuberculosis of testis in infants, 889—Pneumonia in children, 1574—Acute rheumatism in children; Cerebro-spinal meningitis; Contraction of the tendo Achillis; Bilharzia; Œdema of the limbus, 1779

SOUTH-WEST LONDON MEDICO-*CHIRURGICAL* SOCIETY.—Diagnosis and treatment of malignant disease of the cæcum, 170

SOUTH-WEST LONDON MEDICAL SOCIETY.—Some common deformities of children, 592—Constipation and dilatation of the colon, 812—Exhibition of cases, 1037—Early differential diagnosis of abdominal pain, 1037—Cerebro-spinal fluid, 1355

THERAPEUTICAL SOCIETY.—Short notes on a method for rendering creasote and cannabis indica soluble and some little-known medicinal remedies, 295—Control of supernormal arterial pressure, 1163

ULSTER MEDICAL SOCIETY.—Cerebro-spinal meningitis in Belfast, 507—Examination of the urethra and bladder by electric light, 739

Medical officers and the Workmen's Compensation Act, 1442; in crofting counties, question regarding in *Parliament*, 699; of friendly societies, remuneration of, 337; of Scottish Highlands and Islands, 1115; of sick clubs, 618 (see also Poor-law medical officers)

Minchin, Prof. E. A., pathogenic protozoa, 41; demonstration on division of trypanosoma Gravi, 228
Mind, diseases of, tuberculosis in, etiology of, 1613
Mind, Hygiene of (Dr. T. S. Clouston) (review), 594
Mineral springs at Frankston (Victoria), 199
Mineral waters, natural, radio-activity of, 280
Mineral waters of Italy, resources of, 1195
Mineral waters (artificial), Villacabras, aperient, 441; Vivaq, 33
Miners, health of (Parliamentary question), 1562
Mines, disaster in, and breathing appliances, Parliamentary question, 1749; hygiene in, 851; rescue work in (Prof. T. Oliver, 1763; and quarries, *accidents at*, report to Parliament, 1403; (see also Royal Commission on Mines)

MIRROR OF HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

BRADFORD ROYAL INFIRMARY.—A case of congenital diverticulum of the stomach and duodenum in a physiological hour-glass stomach (under the care of Mr. W. H. Horrocks), 1493.—Two cases of purpura hæmorrhagica, one with a peculiar retinal condition, and a case of Banti's disease treated by x rays (under the care of Dr. R. H. Crowley, *Dr. R. Honeyburne, and Dr. H. J.* Campbell), 289
EAST LONDON HOSPITAL FOR CHILDREN SHADWELL, E.—Case of general pneumococcic infection with acute necrosis *of* bone (under the care of Dr. J. A. Coutts), 1648
ELIOT COTTAGE HOSPITAL, *HAYWARD'S HEATH*.—Traumatic popliteal aneurysm (under the care of Mr. C. H. Royser), 165
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Two cases of injury of head in children (under the care of Mr. H. A. T. Fairbank) 89
LEEDS PUBLIC DISPENSARY (SOUTHERN BRANCH).—Case of periarthritis with anæmia and enlarged spleen (Still's disease) (under the care of Dr. J. Gordon Sharp), 166
LIVERPOOL WORKHOUSE INFIRMARY.—Rupture of spleen, splenectomy, recovery (under the care of Mr. W. Alexander), 90
MANCHESTER, ANCOATS HOSPITAL.—Two cases of large ventral hernia (under the care of Mr. E. S. Bishop), 288
MANCHESTER, ROYAL INFIRMARY.—Case of fracture of the pelvis with extensive emphysema of an unusual type (under the care of Mr. George A. Wright), 361
NORTH-EASTERN HOSPITAL FOR CHILDREN.—Case of volvulus of the small intestine in a child aged seven years (under the care of Mr. J. P. Lockhart Mummery), 584
NORTHAMPTON GENERAL HOSPITAL.—Case of large papilloma of the ovary (under the care of Dr. W. M. Robson and Mr. P. K. B Odgers), 1649
QUEEN ALEXANDRA MILITARY HOSPITAL, S.W.—(1) Case of arterio-venous aneurysm of the orbit; and (2) case of gunshot fracture of the femur with division of the great sciatic nerve (*under the care of Major O. G. Spencer*), 1015
ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN.—Two abdominal cases (under the care of Mr. George Morgan), 1015
ST. GEORGE'S HOSPITAL.—Case of skin eruption due to chloretone (*under the care of Dr.* Rolleston), 863
TORBAY HOSPITAL, TORQUAY.—(1) Case of strangulated femoral hernia, herniotomy followed by resection of bowel and circular enterorrhaphy; and (2) case of fracture of the pelvis *from slight violence*, with nipping of small intestine between the fragments causing acute intestinal obstruction and *general peritonitis* (under the care of Mr. Gilbert J. Arnold), 1157
UNIVERSITY COLLEGE HOSPITAL.—Case of femoral aneurysm, excision, cure (under the care of Mr. Bilton Pollard), 1126
WESTMINSTER HOSPITAL.—Case of inoperable cancer treated with *trypsin* (under the care of Dr. Bertram Abrahams), 360

Mitchell, M. M., The Polytechnic Cookery Book (1907) (review), 886
Mitchell Banks memorial lecture at *Liverpool*, 57
Mixed infection in paratyphoid fever in tropics (Dr. A. Castellani), 224
Möbius, Dr. P. J., obituary, 193; *proposed* memorial to, 1103
Moffat, R. U., ice enemata, 55; spirillum fever in Uganda, 266
Moir, Dr. D. M., obituary, 1680
Moissan, M. Henri, death of, 602
Mole, reddened shiny soft congenital tumour diagnosed as, 1165
Molluscum contagiosum, 1678
Monaco, public abattoir at, 547
Mongolian idiot, 1432
Mongolian type of amentia, congenital deformities of, 295
Monkeys, malaria in, 226
Monmouthshire, common lodging-houses in, 692; medical officer of health to, joint appointment proposed, 1325, 1393; proposal negatived, 1676; river pollution in, 195
Mount-stephen, Lord, donation from, to Aberdeen Infirmary, 1394
Monod, Dr. C., the treatment of tuberculosis by Marmorek's serum, 332
Montsarrat, Mr. K. W., nephrectomy for renal sarcoma in children (two cases), 227
Montgomery, Dr. (Claremont Hospital for Insane, West Australia), attacked by lunatic, 1455
Montreal: cremation in, 1251; hospital abuse in, 335; medical inspection of schools in, abandoned, 1123, 1260; typhoid fever epidemic in, 334; *Western Hospital at*, 1818
Montrose Asylum, tragedy at, 1577
Moore, Dr. A. W., *case of scopolamine poisoning*, 1034
Moore, M. E., tests of adulterated quinine (*Looking Back*), 1092
Moore, Dr. F. Craven, case of endothelioma of the stomach, 226
Moorhead, Dr. T. G., specimen after Talma-Morison operation, 294
Moral infection, centres of, 911
Morestin, M., an unusual case *of epithelioma*, 1046
Morgan, Dr. D., and Jones, Mr. R., benign cysts of long bones, 1085
Morgan, Mr. George, two abdominal cases (intussusception and strangulated inguinal hernia), 1015
Morgan, Mr. G. B., *presentation to, by committee* of Sunderland Infirmary, 1177
Morison, Dr. A., operative treatment of adherent pericardium and cardiac hypertrophy, 325; on the condition of the blood-vessels during shock, 686; nature and management of hypertrophy of the heart, 1162; a lecture on causes of cardiac motion and disordered action, 1230
Morison, Mr. J. Rutherford, fibroids *of the* uterine cervix, 354
Morison lectures, abstract of, on insanity, with special reference to prognosis (Dr. A. R. Urquhart), 572, 643, 723
Moritz, Dr. S., *diagnosis of pulmonary* tuberculosis in its earlier stages, 811
Morocco, prevalent diseases in, 26; syphilis in, epidemic spread by flies, 26
Morphine, improved method of determining, 752
Morris, Mr. Henry, on Epsom College, 249; proceedings at recent meeting of General Medical Council: a correction, 1673
Mortality in India from infectious diseases, Parliamentary return regarding, 1158
Mortality from certain diseases, variation in age-incidence (Sir S. F. Murphy), 1566
Mortality, infantile: at Cardiff, 839; in Constantinople, 1679; in Dudley, 1118; excessive in Glasgow, attempts at reduction, 196; in Lapland, 485; in Newport (Mon.), 1611; in Philippine Islands, 962; in Scarborough, 899; at Stirling, 1610, 1611; prevention, 475, lecture on at Royal Sanitary Institute, 1663; question regarding, in Parliament, 628, 1618; at Swinton, prevention by home visitation, 1729; reduction without municipal milk depôts, 510
Mortality of the insane, 519
Mortimer, Dr. J., gastric tetany, 1085
Morton, Mr. A. Stanford, foreign body in right eye, 558; Refraction of the Eye, its Diagnosis, and the Correction of its Errors, with a Chapter on the Use of Prism (review), 366
Morton, Dr. A. S., strychnine, what is a lethal and what a medicinal dose? 481
Morton, Dr. E. Reginald, on the value of the high frequency spark as a local application, 1491; radiographic survey of 170 cases clinically diagnosed as Colles's fracture, 731
Mortuary accommodation at Rugby, improvement in needed, 1513
Moseley, W. H., case of, decided at General Medical Council, 1592
Mosetig-Moorhof, Prof. A. R. von, death of, 1243; obituary, 1397
Moslem, conviviality, *rules of*, 132
Mosquito which communicates yellow fever, new name for, 1262
Mosquito breeding areas in New Jersey, abolishing of, 132
Mosquitoes, classification by larval characters, importance of (Capt. S. R. Christophers), 655

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens, 434—Hæmorrhagic rashes, 1299—Some results of nasal obstruction, 1299—Metritis: some aspects of x ray work, 1654

WIGAN MEDICAL SOCIETY.—Exhibition of cases, 693, 1433; anniversary dinner, 460, 771—Position of, in regard to union of London medical societies, 821

Medical students, preliminary education of, in Germany, 470
Medical Terms, New, Practical Medicine Series, Vol. IX (review), 1306
Medical women in Germany, 618
Medical Women, Scottish Association of, 1394
Medical worthies, forgotten, 93
Medicaments, potent, unification of official formulas for, 627

MEDICINE AND THE LAW.—Action of the police at Manchester in a case of attempted suicide, 607—American law of insanity in relation to crime, 381—American suits (two); Pressure paralysis as an accident and expectancy of life, 607—American tinned provisions, 1036—"At present in good health," legal significance to insurance companies, 805—Barberio's reaction for semen, 608—Bill to abolish the view of the body at coroners' inquests, 760—Burning bodies in private houses, 515—Case of Mr. Burnyeat, M.P., 469—Case of Caleb Charles Whitefoord, 905—Case of an East-end bakery, 607—Case of George Edalji, 1450, 1511—Confidence withheld from a medical man, 113—Control of medical certificates, 1667—Dangerous dogs and the law, 1035—Death of a patient after leaving hospital, the jury's comment, 516—Diagnosis of gonorrhœa, 515—Diagnosis of pathological drunkenness, 1799—Experiments as legal evidence, 1035—"Faked" photographs, 382—Food of the people, 113—Golden rules of medical evidence, 184—Hearsay medical evidence, 1667—Howard de Walden v. Eastes, 1731—Incomplete prescription, 1313—Legal rights of unborn children, 1799—Medical and legal presumption of survivorship, 608—Medical men and coroners' inquests, 1105—Milk and the farmer, 1511—Overlying and accidental burning of children, 760, 968—Plea and test of insanity, 1105—Potters' asthma, 1450—Prescribing druggists, 184, 382—Professional misconduct, 1732—Quackery and touting, 1312—Unregistered person practising dentistry: the alleged attitude of the Home Office, 968—Water-rates for medical men, 760

Medicine and surgery, clinical teaching in, motion respecting, at General Medical Council, 1510
Medicine and the University of Oxford, 751
Medicine: Case Teaching in (Dr. R. C. Cabot) (review), 1435; Congress of, Sixteenth International, date and place of meeting, 1309; Essays in, Æquanimitas (Prof. W. Osler) (review), 96; History of, (Dr. M. Neuburger) (review), 1675; answer to query regarding, 852, works on, 777; Internal, Congress of, to be held at Wiesbaden (1907), 333; proceedings, 1604, 1739; Legal, Handbook of, for Use of Legal Profession (Dr. W. Sellors) (review) 439; Lectures on, to Nurses (Dr. H. E. Cuff) (review), 1232; Pastoral, Essays in (Dr. A. O'Malley and Dr. J. J. Walsh) (review), 1434; practice of (Dr. R. A. Fleming), 436; economic problems of, 321; Preventive, Lectures on (Dr. F. F. MacCabe) (review), 173; relation of the public to (leading article), 955; study of, by women, in Budapest, 768; Text-book of (Traité de Pathologie Interne, par G. Lemoine) (review), 1434; tropical, diplomas in, at Liverpool University, 68; (Dr. T. W. Jackson) (review), [illegible] 1823 1655; trop[illegible] r Edin-
Medicines: [illegible] Patha- derry unio[illegible] ment, 1265; patent, regulations regarding, in Australia, 199; proprietary, action of American Medical Association with regard to (leading article), 1095; foreign, prohibition of importation into Italy, 333; sales in United States, 1792; under new Food and Drugs Act, 373; proprietary, sale of, abroad, 1604
Medico-legal case, 1738; important, in Edinburgh, 914; problem in syphilology, 1614
Medico-Legal Society, banquet, 1617
Medico-Psychological Association, 1331
Mediterranean or Malta fever, 1378 (leading article on), 1372; epidemiology of, 1180; Investigation of Reports on the Commission appointed (review), 1231

Medulla, latent tuberculosis of, intractable hiccough, 750
Meek, Dr. W. O., a rare variety of cardiac degeneration, 1296
Melæna neonatorum, case (Dr. J. B. Page), 1431, 1443, 1513; (Mr. A. R. Gunn), 1618
Melanotic growths, pathology of, in relation to operative treatment (Mr. W. S. Handley), 927, 986
Melbourne, cerebro-spinal meningitis, few cases at, 1464; Inter-colonial Medical Conference to be held at (1908), 769; medical curriculum at, 1464
Memorial fund to Mrs. Craigie, 624
Memorial to Dr. J. E. Dutton, 602; to Dr. James Finlayson, 1813; to Principal Story, 1394
Mendeléeff, Prof., the late, 447; his researches in chemical science (leading article), 370; proposed memorial to, 528
Ménétrier, M., and Clunet, M., a fatal case of anthrax, 394
Meningeal effusion, sterile puriform, with intact polynuclear cells, 1446
Meningitis, with thrombosis of cavernous sinus, 885; with otitic cerebral abscess, 1654; basal, huge inguinal hernia in conjunction with, 590; posterior, 1432
Meningitis, cerebro-spinal, 432, 1433; (Dr. N Raw), 874; case of, 1021; cases, 739; clinical diagnosis (Dr. Cecil Wall), 1211; differentiation of meningococcus from other Gram-negative diplococci in naso-pharynx of cerebro-spinal fever contacts (Dr. R. M. Buchanan), 1690; epidemic of, 373, 449, 552, 604, 676, 740, 753, 826, 963, 1032, 1102, 1181, 1312, 1377, 1589, 1728, 1779, 1791; diagnosis, 552, 687; at Belfast, 259, 311, 331, 469; in Aberdeen, 507, 551, 618, 694, 767, 1120, 1183, 1242, 1256, 1461, 1677; Dr. M. H. Gordon's views, 1326; naso-pharynx as infection carrier in, 1712; opsonic power of serum, with reference to meningococcus of (Dr. T. Houston and Dr J. C. Rankin), 1213; at Constantinople, 1628; in Dublin, 468, 550, 617, 766, 1193; Dundee, 1626; Edinburgh, 616; and Leith, 1255; Glasgow, 392, 397, 617, 1242, 1664; Ireland, 394, 841, 916; Italy, 980; Liverpool, 615; Scotland, 392, 467, 550, 1193, 1394; decrease of, 1460; at Vienna, experiments on prevention of, 1259; micrococcus of, memorandum by Dr. M. H. Gordon to Local Government Board (leading article), 690; precautions of Local Government Board against, 824; questions regarding in Parliament, 625, 626; statistics of, 903, 1445, 1607; etiology of, 545; memorandum regarding, from Local Government Board to ho[illegible] coccal, 432; [illegible] Edinburgh, [illegible] Parliament, 654, 698; occurring in child the subject of [illegible] from cases of [illegible] "spotted fev[illegible] McCleary, 58 [illegible] treatment, 1247; recovery from, under injections of collargol into spinal canal, 106; sporadic, at Melbourne, 1464; spread of, sale of old clothes, question regarding in Parliament, 1267; treatment by anti-meningococcic serum, 687
Meningitis, influenzal, case (Mr. J. S. C. Douglas), 86; serosa spinalis, 1517; tuberculous, without tubercles, 1033
Meningocele, spinal, treated by operation after rupture, 586
Meningococcus, acute cerebro-spinal meningitis due to, 432; differentiation of, from other Gram-negative diplococci in naso pharynx of cerebro-spinal fever contacts (Dr. R. M. Buchanan), 1690; of epidemic cerebro-spinal meningitis, characters of (Dr. M. H. Gordon's memorandum to Local Government Board) (leading article), 698; cerebro-spinal fever occurring in Belfast epidemic, opsonic power of serum, with reference to (Dr. T. Houston and Dr. J. C. Rankin), 1213
Mennell, Dr. Z., use of ethyl chloride, 740
Menschutkin, Prof., proposed memorial to, 528
Menstruation, irregularities in, connexion with irido-keratitis, 1462
Mental diseases, legal importance of, 1117
Mental disorders, incipient treatment at Western Infirmary, Glasgow, 693
Mental disturbances of heart disease, 619
Mercantile Marine Service, Italian, tuberculosis, 1816
Mercier, Dr. C., meditations on gout (written during an attack), 1646
Mercury, rôle of, in modern therapeutics, 1055; cyanide of, intra-orbital injections in treatment of sympathetic ophthalmia, 962; salicylate in treatment of syphilis, 308; and sulphur waters treatment, 1747

Mering, Prof. von, and Winternitz, Dr., the influence of certain drugs on the temperature of the living body during exposure to heat, 1740
Merrick, Dr. Alexander Stewart, obituary, 59
Merthyr Tydvil, new isolation hospital at, 987
Mesenteric glands, caseous, volvulus of small intestine round, 294
Mesentery, cyst of, incision and drainage, 93
Metabolic product, albuminoid, of a bacillus, chemically altered, successful in treatment of tuberculosis and leprosy (Dr. S. F. Wernich), 1005
Metabolism, Pathology of (Prof. C. von Noorden) (review), 1654; Physiology of (Herr A. Magnus-Levy) (review), 1654; Animal, Problems in (Dr. J. B. Leathes) (review), 171
Metabolism in fever, 226
Metal, action of potable spirits on, 328
Metallic contamination of meat essences kept in tins, 42
Metastases, formation of, in groin, in case of sacro-coccygeal teratoid tumour (Mr. S. Pringle), 1021, 1643
Metatarsal bone, fifth, fracture of base of (Mr. H. Burrows), 1083
Metatarsal bones and first inter-metatarsal space, multiple chondromata of, 293
Metatarsus, dislocation of, outwardly, and of first cuneiform bone, 979
Metchnikoff, M. Elie, the New Hygiene; three lectures on the prevention of infectious diseases (preface by Prof. R. Lankester), 1906 (review), 209
Meteorological daily readings, 136, 205, 267, 341, 559, 631, 703, 778, 852, 925, 991, 1059, 1133, 1205, 1336, 1407 1474, 1540, 1689, 1754, 1826
Meteorological record, December, 1906, to March, 1907, 1097
Meteorological reports: January at home and abroad, 445
Metric system, advantages of, 612
Metritis, 1654; chronic (see also Uterus, inflammation of, chronic)
Metropolitan female sanitary inspectors, 1240
Metropolitan Hospital Sunday Fund: (leading article), 1580; changes on councils and committees, 180; special supplement, 1543; contributions and bequest of late Mr. Herring, 1543; demands of over-growing population, 1544; development of the Fund by the late Mr. T. H. Wakley, 1543; increasing demand for metropolitan hospitals, 1544; list of donations, 1728; receipts and payments for year ending Oct. 31st, 1906, 1550; results of collection since commencement of Fund 1549; statistics of hospital work in London during 1906, 1545, 1546; relating to, in cottage hospitals and convalescent homes, 1547; relating to dispensaries and nursing associations, 1548
Metropolitan Street Ambulance Association, 1803
Metropolitan Street Ambulance Service, 449, 543, 674
Metz, small-pox at, 1604; question regarding, in Parliament, 1199
Mice, incidence of spontaneous cancer in, 168; inoculated with cancer, hydrochloric acid in stomachs of, 220
Micholli, Mr. Pietro, C.M.G., complimentary dinner to, 247, 553
Microbic (Hepatitic), cyanosis, 972
Micrococci, *de novo* origin of, in certain previously super-heated saline solutions contained within hermetically sealed tubes, 225
Micro-organisms on dirty blotting pads, 179
Micro-organisms (pathogenic), effect of exposure to tobacco smoke on the growth of (Dr. Miles B. Arnold), 1220
Microscopy, developments in since 1871, 663
Microsporon Audouini, affecting a hair, 741
Middlesex Hospital, 624; festival dinner, 1242, 1365
Midland Counties Home for Incurables, 390
Midwifery, aseptic and septic, at Liverpool Workhouse Infirmary (Dr. W. Alexander), 940; Instruction in, for Nurses (Dr. H. R. Andrews) (review), 1023; discussion regarding, at General Medical Council, 1593; students of London County Council scholarships for, 936; unqualified, 557
Midwifery forceps, application of, 739
Midwives, unregistered, at Truro, 337; examination for: history of their conduction by the Obstetrical Society of London (Dr. C. J. Cullingworth) 629; (leading article on), 620; relations with parish medical officers, 539; certified, scarcity of, in Loughborough district, 624; training of, question regarding, in Parliament, 1199 (see also Parish midwives)

Midwives Act, action of Devon county council with regard to, 840; administration of, at Cardiff, 1744; discussion on, 868; action of general practitioners in relation to, 976; and London County Council elections, 448; payment of medical men under, 824; working of, in Lancashire, 1393
Midwives Board (see Central Midwives Board)
Milan, abattoirs of, 613; post-graduate cliniques at, 280; sero therapeutic institute at, 130
Miles, Mr. W. Ernest, undesired publicity, 717
Military defence of empire discussed at Colonial Conference, 1185
Military doctors, attendance of, at civilian casualties, question regarding, in Parliament, 953
Military home hospitals, reserve, 1383

Obstetrical Society of London: history of its examinations for midwives (*Dr. C. J. Cullingworth*), 628; (leading article on), 620
Obstetrics, exophthalmic goitre in relation to, 812
O'Carroll, Dr. J. F., suffocative hydrothorax, case, 293
Occipito-posterior presentation, method of delivery by forceps in difficult cases, 512
O'Connor, Dr. Y. E., combined sanitary districts, 811
Oddities, examination, 1825
Ödön, Dr. R., modified cow's milk for infant feeding, 1817
Odgers, Mr. P. N. B. and Robson, Dr. W. M., a case of large papilloma of the ovary, 1649
Odontological Society of Great Britain, jubilee dinner, 401
Œdema, angio-neurotic, cases exhibited, 512; in infant, 295; of Bright's disease, pathology, 1605; of limbus, 1779
Œsophagus, abnormal development of (Dr. J. E. Spicer), 157; cancer of, of unusual type (Dr. E. Pratt), 423; diphtheritic membrane involving pharynx, œsophagus, and respiratory passages (Dr. F. E. Field), 161
Oil (see Grey oil)
Okol disinfectant, 441
Old age, pathology of, 26
Old Bailey, accident at, in 1807, 673
Oldbury, Hospital Saturday collection at, 1675
Oldham, Mr. C. J., bequest to Manchester Grammar School, 765
Oldham, Hugh, descendant of, 765, 910; Mr. R. S., "a descendant of Hugh Oldham," 910
Oliphant, Dr. E. H. L., medical science in Scotland during the time of the Reformation and at the time of the Union of 1707, 364
Oliver, Dr. G., control of supernormal arterial pressure, 1163; some notes on the control of supernormal arterial pressure, 1346; Studies in Blood Pressure, Physiological and Clinical, 1906 (review), 1299
Oliver, Prof. T., rescue work in mines: lessons from the Courrières mine catastrophe in France, 1768
Oliver-Sharpey lectures on new facts in relation to the processes of nervous degeneration and regeneration (Dr. W. D. Halliburton), 1207, 1273; (leading article), 1303
O'Malley, Mr. C., medical education and the University question in Ireland, 1249
O'Malley, Dr. A., and Walsh, Dr. J. J., Essays on Pastoral Medicine, 1906 (review), 1434
Ombredanne, M., severe gunshot wounds of, operation, 1815
Omentum, torsion of, operation for, 1517
Omnibus flag, soiling of, 1179
Ontario: Deportation of insane from, 335; hospital association organised in, 1122; Medical Association, annual meeting, 1818; Medical Association and a Ministry of Health, 1122; Medical Council, antagonism to the Canadian Press Association, 620; list of members, 620; practice of quackery in, 620; typhoid fever epidemic in, 334
Open-air school, 836; swimming bath at Leeds, 467; spaces in Birmingham, 57; Association, 1392, 1675
Openshaw, Mr. T. H., exhibition of surgical cases at Hunterian Society, 1021
Operateurinstitute, Vienna, centenary of, 981
Operations, surgical, estimate of risk of ("The surgeon's power of life and death"), 543; leading article), 101
Ophthalmia, in Benghazi in Tripoli, 1764; gonorrhœal, remedies for, 425; sympathetic, treatment by intraorbital injections of cyanide of mercury, 962
Ophthalmitis, metastatic, 232
Ophthalmologists, question for, in case of George Edalji (Sir Arthur Conan Doyle), 189; (see also Eye, diseases of)
Ophthalmology, annual course of, at Oxford University, date, 1821
Ophthalmoscope, diagnosis of case of tuberculosis only after examination by, 588
Opium, decoction of, made by nurse, causing death of infant, 129; habit, reported remedy for, Parliamentary question, 1538; medicinal, cultivation in India, 107; smoking in Galata, 846
Oppenheimer, Dr. S., Surgical Treatment of Chronic Suppuration of the Middle-ear and Mastoid (review), 365
Opsonic chart of tuberculosis: observations on induction of auto-vaccination by x rays (Mr. H. D. McCulloch), 215
Opsonic index and opsonins and their practical value in the treatment of disease (Dr. G. A. Crace Calvert), 279; regulation by, of inoculations of vaccine prepared from organisms found in patients' blood, successfully made in the case of infective endocarditis (Sir J. Barr, Dr. W. B. Bell, and Capt. S. R. Douglas), 499; taken from eye-ball filled with tubercle, 429; technique, 435; use of, in diagnosis of tuberculosis, 809; to Various Organisms in *Sane* and *Insane* (Dr. C. J. Shaw), 1287; power of serum, with reference to the meningococcus of cerebro-spinal fever occurring in Belfast Infirmary (Dr. Thomas Houston and Dr. J. C. Rankin), 1213
Opsonin and immune serum, combining properties of, 226
Opsonins (Dr. J. L. Bunch), 144; discussion on, 27; and immunity (Dr. J. L. Bunch), 873; and opsonic index and their practical value in the treatment of disease (Dr. G. A. Crace-Calvert), 279
Optical treatment of strabismus, 1678
Opticians: ophthalmic, duties of, 1473; testing of children's eyesight not to be relegated to, 1032
Orbit: aneurysm of, arterio-venous (Major C. G. Spencer), 1015; removal of melanotic sarcoma from, by Kronlein's operation (Mr. W. G. Sym), 658
Orchitis parotidea or testicular mumps, 118
"Oregogenic" function of thyroid body, 767
Oriental nations, timorousness of, 197
Orme, Mr. W. B., the fourth class of the Imperial Ottoman Order of the Medjidieh conferred on, 46
Oronbyatekha, Dr., the late, 752
Orr, Dr. D., and Rows, Dr. R. G., lesions of the cranial nerves in general paralysis of the insane and of those produced experimentally in animals by the action of toxins, 663
Orton, Dr. G. H., and Walsham, Dr. H., Roentgen Rays in the *Diagnosis of Diseases of the Chest* (review), 437
Osborne Convalescent Hospital (question in Parliament), 1055
Osiris, M., large bequest to Pasteur Institute, 394
Osler, Prof. W., abdominal tumours associated with disease of the testicle, 1409; *Æquanimitas* (review), 95; visit to Canada from England, 334
Ossicles, treatment, successful, of chronic suppuration of middle ear without removal of, 231; (Dr. F. Spicer) 61; (Mr. C. J. Heath) 1146
Ossiculectomy or otectomy, 232
Osteitis, syphilitic, 889
Osteitis deformans, case of (Dr. R. Waterhouse), 1215; skeleton of typical example, 1215
Osteo-arthropathy, pulmonary, hypertrophic, 1102; in congenital heart disease (Dr. H. Batty Shaw and Mr. R. H. Cooper), 880, 884
Osteogenesis imperfecta, 884
Osteolipoma of the brain, 1650
Osteomyelitis, tuberculous, partial resection of tibia for, 1431
"Osteopaths" (practisers of quackery) in Ontario, 620
Osteopathy, Bill to regulate practice of, in United States, 395, 962
Otorrhœa, chronic, operation, recovery, 1364
Otectomy (see Ossiculectomy)
Otis, Dr. W. K. (the late), tribute to his memory at meeting of American Urological Association, 46
Otitis media: (acute), treatment of, 589; followed by cerebellar abscess, 1229; suppurative, chronic, 1159; case exhibited, 948
Otitis, suppurative, lumbar puncture in complications of, 618
Otology, Handbook of (Dr. F. Bezold) (review), 1367 (see also Ear, diseases of)
Otomasseur, electric, 1364
Ottery St. Mary Cottage Hospital, 402
Oughterard, typhus fever at, 1193; question regarding in Parliament, 1200
Our Sons: Their Start in Life; reprinted from the *Guardian*; second edition (review), 1657
Out-patients, surgical affections frequently met with in, 233
Ovarian ligament, right, tumour of, 512
Ovary: carcinoma of, specimen, 810; cyst of, after-history of case of fibroid of broad ligament associated with, 735; bilateral axial rotation during pregnancy, 1160, 1161; dermoid, specimen, 434, 1433; multilocular, successfully removed from infant (Mr. C. W. MacGillivray), 1467; removal of, paratyphoid fever following (Dr. W. Thyne), 1293; ruptured, 1087; specimen, 94, 590; tubal pregnancy, associated with (Dr. E. G. E. Arnold), 1490; fibroma (double) of ovaries complicating pregnancy, 27; fixed in pelvis, specimen, 513; fibromyoma of, 232; specimen, 590; fibrosis of, and x rays, 1753; myoma of, specimen, 1087; papilloma of (Dr. W. M. Robson and Mr. P. N. B. Odgers), 1649; tumour of, 1494; complicating pregnancy, 27; malignant, specimen, 1160
Overcrowding in relation to infant mortality in Budapest, 131
Overhead wires on tramways, dangers of, 311
Overlying of children, 329, 760, 968
Ovine teratology, 1825
Owen, Mr. E., Cancer: Its Treatment by Modern Methods, Bradshaw Lecture for 1906 (review), 893; use of alcoholic beverages, 1110
Owen, Dr. J., appointment at Liverpool Stanley Hospital, 690
Owens, Dr. J. S., and Des Vœux, Dr. H. A., gas fires, 189
Oxalic acid, poisoning by, fatal case, 1165
Oxford Eye Hospital, 847
Oxford, University of, 402, 474, 553, 623, 773, 883, 1401, 1680, 1749; date of annual course on ophthalmology, 1821; election to Chancellorship, 846; degree days and examinations, 262; graduation, 336; medical news of, 846; and medicine, 751; Romanes lecture (1907), 262; School of Medicine, examination results, 62 (see Radcliffe Infirmary); text of Latin speech at Professor Ehrlich's introduction for honorary degree of D.Sc., 1821
Oxley, Dr. A. J. Rice, appointed Physician-in-Ordinary to Her Royal Highness Princess Henry of Battenberg, 528
Oxygen, continuous use of, in case of bronchopneumonia in cardiac subject (Dr. Bernard Myers), 360
Oxylithe, 440
Oysters: cause of typhoid fever, 1257; from Cette, causing epidemic of typhoid fever, 551
Ozæna, treatment of, by injections of solid paraffin, 1612
Ozonair machine, description of, 1640

P

Page, Mr. F. J. M., Elements of Physics for Medical Students, 1907 (review), 1300
Page, Dr. J. B., case of melæna neonatorum, 1431
Paignton, sanitary administration in, 822, 1041; water supply of, 1727
Pain (see under names of Organs and Regions)
Paine, Dr. A. E., death from an electric shock whilst handling a telephone receiver and an electric light lamp, 246
Paint, smell of, causing distress and disturbance of health, 1029
Paisley Infirmary, gifts to, 1814
Palate: circumscribed tumour of, 233; hard, syphilitic perforation of, plastic operation for, 293
Palgrave's Golden Treasury, with Additional Poems (World's Classics, vol. cxxxiii) (review), 1368
Palmer, Mr. J. Foster, treatment of apoplexy, 1161
Palmer, Miss Margaret D., Lessons on Massage, third edition (review), 1168
Palmer, Dr. W. H., mercury salicylate in the treatment of syphilis, 308
"Palmine" vegetable butter, 745
Panama canal zone, health in, 1614
Panama, isthmus of, sanitary work on, 1507
Pancreas: affections of (Dr. S. Phillips), 418; case after operation for, 834; cyst of, rupture, certain diseases of (Dr. S. Phillips), 503; diagnosis by pancreatic reaction of urine and associated methods, 25; secretion of, 1740

Pancreatic extract and secretin in relation to diabetes, 62; reaction in urine in diagnosis of diseases, 26
Pancreatitis: acute, etiology of, 1445; acute hæmorrhagic, 227; in case of strangulated hernia (Mr W. H. Brown), 806; acute simple catarrhal (Dr. S. Phillips), 563
Papilloma, true, of bladder, specimens of, 232; of ovary (Dr. W. M. Robson and Mr. P. N. B. Odgers), 1649
Papillomata of bladder caused by bilharzia hæmatobia: removal by suprapubic cystotomy, 585
Paraffin, injection of, in treatment of atrophic rhinitis, 1554; solid, injections of, in treatment of ozæna, 1612
Paralysis: agitans, case of, 94; of third cranial nerve, 295; of cranial nerves, significance of, 265; complete, of gastrocnemius and soleus with talipes calcaneus, treatment by nerve-grafting, 834; general, of the insane, in a boy, 428; case with atypical symptoms, 295; lesions of cranial nerves in, 665; localisation of, 1115; infantile, case, 1431; Landry's, case of, 94; post-operative, facio-hypoglossal anastomosis for, 824; pseudo-hypertrophic muscular, early case 512; recurrent, of ocular muscles in subject of hæmophilia, 650; right, of larynx, 233; (spasmodic spinal), treated by radiotherapy, 841; of left vocal cord, 812; of vertical movements of both eyes, 588 (see also Erb's paralysis, Pressure paralysis)
Parapsoriasis of Brocq, 741
Parasacral incision in removal of urethral calculus, 1021
Parasite in African Tick Fever, Experimental Study (Dr. A. Breinl and Dr. A. Kinghorn) (review), 23
Parasite of sleeping sickness, life cycle of (Mr. J. E. Salvin Moore and Dr. Anton Breinl), 1219
Parasitic theory, prophylaxis of cancer as indicated by, 327
Parathyroid glands in man, 587; histological study of, 587; changes in, in fatal case of myxœdema (Dr. D. Forsyth), 154
Paratyphoid fever: B bacillus of, infection by (Dr. E. A. Gates) 1571, bacteriological diagnosis of, 1241; following removal of an ovarian cyst (Dr. W. Thyne), 1293; in Mauritius, case of (Lieut. Col D. B Spencer and Capt. H. E. Staddon), 75; in the tropics, cases of mixed infection (Dr. A. Castellani), 824
Paresis, spastic, of left arm, with cyanosis of hand, 427, 428
Paris, abattoir at La Villette, 123

Stornoway, appointment of medical officer of health for, 1814
Storry, Mr. F. W., obituary, 1329
Story, Principal, memorial to, 1394; obituary, 196
Stout, oatmeal, 1783
Stovaine: *references to*, 404; spinal anæsthesia with, 45
Stowers, Dr. J. H., case of small nodule upon right cheek, 296; multiple warts, 741
Strabismus, optical treatment of, 1678
Straits Settlements: Mr. D. J. Galloway, appointed member of Legislative Council, 1503; public health in, 474
Strangeways, Mr. L., *medical law and limited* companies, 909
Street accidents *in London* (Parliamentary question), 1200; in Manchester, 1743
Street *collection* by ladies for charity in Copenhagen, 1463
Street newsvendor, 1663
Streets, cleansing of snow from, 44
Streptococcus pyogenes, infection of conjunctiva with, 429
Streptococcus wound of finger (Dr. W. P. Cowes), 583
Stretton, Mr. J. Lionel, treatment of distension of the intestines, 836
Stritch, Mr. G. R. Seymour, new form of pessary, 94; the State and *syphilis, 1228*
Strontium bromide, in treatment of epilepsy in insane (Dr. J. M. Bonnion), *19*
Strophanthus, physiological action of, 1462
Struthers, Mr. John W., *patient after recovery* from chronic intussusception with inversion of the vermiform *appendix*, 94; *Local* Anæsthesia in General *Surgery* (*review*), 235
Strychnine: *poisoning by*, fatal cases, 1165; *what is a lethal and what is a medicinal dose*, 461
Stuart-Low, Mr. W., the use of animal blood *serum in surgery*; preliminary notes, 1221
Students: of Scottish universities, conference at Edinburgh, 258; matriculation at Glasgow and Edinburgh (1906), 196
Sturge, Miss M. D., and Horsley, Sir V., Alcohol and the Human Body (review), 1714
Subdural hæmorrhage, traumatic, in infant, no lesion of skull (Mr. H. A. T. *Fairbank*), 89
Submucous resection of nasal septum, 588
Sugar: new test for (*Dr. H. J. H. Fenton*), 215; in urine, estimated by means of caustic alkali, 1446; *estimation*, 1603, 1673, 1693; singular action of arsenic acid on several sorts of (*Looking Back*), 237
Suggestion and Psychotherapy, or *Hypnotism* (Dr. A. Forel) (review), 1576
Suicide: *attempted, at Manchester*, action of police, 466, 607; in Italy, 601; and sanity (Dr. T. C. Shaw), 1087
Suicide bureau, established by Salvation Army in New York, 932
Sulph-hæmoglobinæmia: idiopathic cyanosis due to, 225; (Dr. S. West and Dr. T. W. *Clarke*), 272; (leading article), 443, 687; and cyanosis, spectrum of blood *of* patient *suffering from*, 659
Sulpho-ricinate of soda with salicylic acid in treatment of *pharyngo-keratosis*, 1248, 1316, 1456
Sulphur in foods, percentage of, 923; in London smoke, effect on public buildings, 1585; waters and mercurial treatment, 1747
Summer, effects of cold weather in, 1674
Sunday observance, origin and meaning, 744
Sunderland Infirmary, presentation *to* Mr. G. B. Morgan by committee of, 1177
Sunnyside Asylum, Montrose, homicide at, 1610
Sunshine: bright, during March, 1907, 961; recorded in British Isles during 1906, 215; number of hours recorded during 1906, 678; *lack of*, in *Manchester* from continuous smoke, 823
Suppuration, chronic, of middle ear, treatment without removal of drum, membrane, and ossicles (Mr. C. J. *Heath*), *1146*; in wound after cataract extraction, 660
Suprapubic *operation*, successful *removal of* large vesical calculus by (Mr. H. Littlewood), 422
Suprarenal capsules, disease *of*, "white line" *as symptom of*, 901
Suprarenal *gland*: *hæmorrhage into, specimens showing*, 95; *new growths of*, 95; glands, morbid histology of, 1296
Surbiton urban district, *report* of medical officer of health, 1313
Surgeon, English, a famous, as a quack in Melbourne, 924
Surgeons and barbers, relations anciently existing between, 604
Surgeons, responsibility *of*, in *operating* ("The surgeon's power of life and death"), 458, 643, 762, (leading article), 101
Surgeons to shipping companies, imposition of extra duties upon, 1058
Surgery: after-treatment in (Dr. B. C. Stevens), 1481; American, Account of (C. H. Rutherford) (review), 1577; intervention *of*, necessitated by accidents and diseases at *Christmastide*, *38*; *renal function in relation* to (Mr. J. W. Thomson Walker), 711, 792; use of animal blood serum in (Mr. W. *Stuart-*Low), 1221; use of clay in, 44
Surgery, General, *Local Anæsthesia* in (Mr. J. W. Struthers) (review), 235
Surgery, General, Practical Medicine Series, comprising Ten volumes *on the* Year's Progress in Medicine and Surgery, vol. II., edited by John B. Murphy, M.D., 1906 (review), 743
Surgery, of Emergencies (Traite de Chirurgie d'Urgence) (Prof. F. Lejars (review), *743*
Surgery and medicine, clinical teaching in, motion at General *Medical Council*, *1510*
Surgical affection frequently met with in out patients, 233
Surgical clinics at Budapest, general anæsthetics in use in, *395*
Surgical reform, *1829* (*Looking Back*), *302*
Surgical treatment of colitis (Mr. J. P. Lockhart Mummery), *1638, 1649*; *by* unqualified practitioner, ill results of patient's *preference for*, *1203*
Survivorship, presumption of medical and *legal*, *608*
Sutherland, Dr. G. A., congenital cerebellar ataxy, case, 295; *congenital* deformities of so-called Mongolian type of *amentia*, *295*; "Punch"-like intonation in syphilitic infant, 591; medical *treatment of congenital* pyloric stenosis, 725; osteogenesis imperfecta, 884
Sutherland, Mr. J. A., *obituary*, 199
Sutures: buried, and ligatures, with special reference to catgut (Mr. A. E. Johnson), 1074; surgical, strength of, *242*
Swansea General *Hospital*, *abuse of*, as charity organisation, *323*
Swansea rural district, typhoid fever in, 1325
Swanzy, Mr. Henry, and Werner, Dr. Louis, A Handbook of the Diseases of the Eye and their Treatment (review), *365*
Sweated Industries, National Conference on, 1814
Sweated labour, appointment of committee by Glasgow corporation to consider, 128

University College Hospital, appeal for funds, 1758; meeting of Ladies' Association, 1098
University College Medical Society, 698
University College of North Wales, 1193
University College, Oxford, decision to endow prize for research in medical science, 751
University at Frankfort, proposal for, 198
University guild of graduates at Birmingham, 56
University intelligence, *foreign*, 216, 336, 473, 771, 1127, 1196, 1401, 1748
University question in Ireland, 331, 393, 458, 617, 821, 1249, 1267
Universities, Scottish, *preliminary* examinations in, 196; of Scotland, reform required under Carnegie Trust, 467 (see also *under* Cambridge, Durham, Edinburgh, Glasgow, Leeds, Liverpool, Oxford, Sheffield, Victoria of Manchester)
Universities, foreign, 623
Uræmia, specimen from fatal case, 1494
Urea, estimation in urine, 609
Ureter, calculus removed from each, for *double pyonephrosis*, 293
Ureters, catheterisation of, new aseptic sheath for, 1233; implantation into rectum, specimen, 948; pressure of tumour on causing acute albuminuria, 169
Urethra, carcinoma of, primary, 1494; examination of, by electric light, 739; *ruptures* of, intrapelvic and perineal (Mr. E. Deanesly), 81; septum of, causing obstruction to urinary outflow in case of hydro-nephrosis (Mr. G. S. Thompson), 506; syringe for, modified, 237
Urethroscope, new, 469
Uric acid, determination of, new methods for (Dr. A. F. Dimmock and Mr. F. W. Branson), 14
Uric meter for measuring uric acid in urine, demonstration of, 364
Urinary diseases, balneological treatment of (Dr. O. Kraus), 1151, 1222; organs, diseases of, lectures on, at Necker Hospital, Paris, 825; tract, tuberculosis of, 737
Urine, acetone in, detection of, 911; tests for (Mr. J. F. Jacksontaylor), 805; detection of acetone in, 624; acidity of, 340; estimation of urea and hydroxybutyric acid in, 609; extravasation of, fatal (Mr. Raymond Johnson), 592; outflow of, checked by urethral septum in case of hydronephrosis (Mr. G. S. Thompson), 506; pancreatic reaction of, in diagnosing disease of pancreas, 26; specific gravity in, 252; sugar in, estimated by means of caustic alkali, 1446; suppression of, post-operative, treatment by sparteine sulphate, 960; temperature of, as means of thermometry, 394; testing by Bright's method, physiological and pathological observations (Dr. D. McCay), 1483; and blood, in health and disease, electrical conductivity of, a test of functional efficiency of kidney, 229
Urquhart, Dr. A. R., delivery of Morison lectures by, 392; abstract of the Morison lectures on Insanity, with Special Reference to Prognosis, delivered before the Royal College of Physicians of Edinburgh on Jan. 28th and 30th and Feb. 1st, 1907, Lecture I., 572; Lecture II., 648; Lecture III., 723
Urticaria, treatment of, by calcium chloride, 1120; *pigmentosa, case*, 1432
Usk, river, pollution of, 195
Uterine dilator, exhibition of, 1227; vessels, arterio-sclerosis of, and intractable uterine hæmorrhage (Dr. Elizabeth Macdonald), 169
Uterus, absence of, in three sisters and two cousins (Dr. L. N. Boston), 21; appendages of, inflammatory diseases, treatment, surgical, 1365; inflammation, chronic, 91; and *appendages, tuberculous disease of*, causing primary amenorrhœa, 1161; backward displacement of, ventrofixation in treatment of, 228; cancer of cervix and fundus of, 94; cervix of, carcinoma of, pathology, 890; fibroids of (Mr. J. Rutherford Morison), 354; fibroid of, 810; exhibition of, 363; intra-peritoneal bleeding from, with acute distension of abdomen (Mr. W. Bruce Clarke), 8; large, removal, 1160; specimen, 690; fibroids of (Dr. A. E. Giles), 574, 653; complicating pregnancy, hysterectomy, 512; tumours of, treatment by operation, summary of cases (Dr. A. E. Giles), 574, 653; pregnancy in rudimentary uterine horn, two cases, 1652; fibromyoma of, diffuse, 429; fibromyoma of, specimen, 513; in fundus, and cancer in cervix, 886; inflammation of, chronic, 91; pathology of, 192; perithelioma of, 735; prolapse of, radical cure of, 1087; removal, for cancer of cervix, 233; with contained fœtus and placenta, 232; excision of (see Hysterectomy); ventrofixation of, modification in technique of, 811; vessels of, arterio-sclerosis of, 169; wall of, sutured by iodised cat-gut *after Cæsarean section*, 27; (see also the Appendages, *uterine*); (see also *Cervix*)

V

Vacancies, weekly list of, 64, 135, 202, 264, 338, 402, 476, 556, 628, 700, 776, 850, 939, 1056, 1131, 1202, 1268, 1334, 1472, 1538, 1404, 1686, 1752, 1824
Vaccination, certificate of exemption from, and conscientious *objector* to (leading article), 593; conscientious objectors to, question in Parliament, 1199; debates on, in Parliament, 554; *fees for*, question in Parliament, 625; illness following, question in Parliament, 933; in Algeria, 1678; in the Philippines, 1262; in Scotland, questions in Parliament, 625; influence on whooping-cough, 1395; legislation, new, 1738; in treatment of aneurysm by anastomosis (Looking Back), 1454; (new) (leading article), 1499; refusal of exemption from, by magistrate, question in Parliament, 1055; unvaccinated children in Derby, question in Parliament, 1199; and emigration, Parliamentary question, 1332; and the London County Council election, 909; (see also Auto-vaccination)
"Vaccination Act, 1907," 1307; *Acts, petition* for repeal of, 1403; Bill, 1265; administration, Parliamentary question, 1684; discussion on second reading, 1537; *declarations* under the, Parliamentary *question*, 1333; officers, payment of, question in Parliament, 1472
Vaccination officers, fees of, 1822
Vaccination Order, 1806; *question in Parliament*, 699, 1128, 1257; *criticism of*, 1602; Parliamentary committee, 1751
Vaccinator, public, a, action of St. Columb *board of guardians with respect to*, 127
Vaccinators, public, fees of, 764; long service of Mr. J. B. Hughes, 194
Vaccine, inoculation of, from organisms found in patient's blood, in successful treatment of infective endocarditis (Sir J. Barr, Dr. W. B. Bell, and Capt. S. R. Douglas), 499; for the army, 1823
Vaccines, acute pathogenic infections treated with, 886; bacterial, treatment by (J. L. Bunch), 144
Vagal and vaso-vagal attacks, *1804; (Sir W.* Gowers), 1551
Vagina, cancer of, 1653; malignant polypus of, secondary to adrenal tumour of kidney, 1297; primary embolic chorion-epithelioma of, 1652; rupture of, with protrusion of bowel, 232; safety pin removed from, *exhibited*, 512
Vagrancy (Sir William Chance) (review), 32
Vaillard, M., and Dopler, M., antidysenteric serum, 1121
Valerian juice, fresh, pharmacology of an alkaloid *found in*, 900
Vallas, Dr., cancer *of the pharynx*, 197
Valois, Dr. G., intra-orbital injections of cyanide of mercury in sympathetic ophthalmia, 962
Valvular disease and dextrocardia in a boy, 1365
Vanilla, eruption on worker in, 469
Variation, Recent Progress in Study of (Mr. R. H. Lock) (review), 1022
Varicella, confluent hæmorrhagic eruption in (*Mr. C. R. Porter*), 1359
Varot, M., evils of cocoa in feeding of young children, 394
Vas deferens, irrigation and drainage of the seminal vesicle through, 1099
Vaughan, Mr. J. C. F. D., pneumothorax from puncture of the pleura, 84
Vazifdar, Mr. N. J. F., a case of dermoid cyst in the ramus of the jaw, 83
Vegetable butter, "palmine," 745; jellies, nutritive value of, 447
Vehicles, public, hatpins in, 750
Venereal Disease and Syphilology (Mr. C. F. Marshall) (review), 172; diseases, society for the prevention of, 1513, 1673; statistics of, in Austro-Hungarian army, 261 (see also German Congress for)
Venoms and Toxins (E. P. Escot) (review), 665
Venous radicles, telangiectasis of, 1574
Ventilation of hats, an experiment, 924; of sewers in Manchester, 67
Ventricle, left, rupture of (Dr. R. A. Forster), 583; single, specimen exhibited, 1162
Ventrofixation in treatment of backward displacements of uterus, 228; of uterus, modification in technique of, 811
Vercelli, abattoirs at, *613*
Verdun Hospital, Quebec, 620
Verebély, Dr., the pathology of sciatica, 619
Vernon-Harcourt, Mr. L. F., Sanitary Engineering with Respect to Water-supply and Sewage Disposal, 1907 (review), 992
Vertex presentation, dorsal displacement of arm in, 462; (Dr. A. G. Wells), 165
Vest pocket *inhaler*, 33
Veterinary Medicine: Blood Serum-therapy, Preventive *Inoculation*, and *Toxin* and Serum Diagnosis Applied to (Mr. Walter Jowett) (review), 172
Viavi treatment, 65
Vibrator, the Barker, 1688
Vibriones, *de novo* origin of, in previously super-heated saline solutions contained in hermetically-sealed tubes, 225
Viceregal Commission on Poor-law in Ireland, 840; Poor-law policy with regard to tuberculosis, 591; report of, 591
Victoria, epidemic diseases in, 1464; health of, 1819; health administration in, 1464, 1819; prevalence of disease in, 620; promotion of pure milk-supply, 199; Medical Society of, amalgamated with Victorian branch of British Medical Association, 620

Tiverton, diphtheria in, 1331

Tiverton Infirmary, 1264

Tobacco, amount spent on, in Liverpool workhouse, 1393; consumption in Austria, 131

Tobacco, smoke of, effect of exposure to, on the growth of pathogenic micro-organisms (Dr. Miles B. Arnold), 1220; pungency of, 1097

Todd, Dr. J. L., decoration of Cross of Commander of the Order of Leopold II. conferred upon him, 109

Todd, Dr. J. L., and Kinghorn, Dr. A., review of the present means of combating sleeping sickness, 282

Tokio, British Legation at, medical officer at, nationality of, 1029

Tokio, British Embassy at, medical officer to, question in Parliament, 1268, 1404

Toller, Mr. Ebenezer, obituary notice, 622

Tomlinson, Mr. J. H., a "longarm" for use in retinoscopy, 668

Tongue, base of, ulceration of, and of epiglottis, 233; lymphangioma of, 590; method of diminishing raw surface after removal of half, 293; removal of half, by Whitehead's method, 1162; tumour of, in boy, aged five years, 1227 (see also Calculi, sublingual)

Tonsil, removal, followed by enlargement of cervical glands, 233; "tuberculoid" disease of, 812

Toogood, Dr. F. S., discussion on the Midwives Act (1902), 888

Tooth (displaced), in nasal cavity causing fœtid vomiting, 1259

Toronto, Board of Trade of, protests against admission to Canada of tuberculous immigrants, 335; nurses' home opened in, 620; University of, gift on the Nobel plan, 620

Toronto Provincial Hospital for the Insane, appointment of resident pathologist to, 335

Torque, twisted metal collar worn round neck by ancient Gauls, 629

Torsion of the testis (Mr. H. M. Rigby and Mr. R. J. Howard), 1416

Torulæ, *de novo* origin of, in certain previously super-heated saline solutions contained within hermetically sealed tubes, 225

The Ingleby Lectures

ON

PELVIC INFLAMMATIONS IN THE FEMALE.

Delivered at the University, Birmingham, on May 9th and 16th, 1907,

BY THOMAS WILSON, M.D. LOND., M.CH. BIRM., F.R.C.S. ENG.,

OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM.

LECTURE II.

Delivered on May 16th.

SYMPTOMS AND COURSE.

MR. DEAN AND GENTLEMEN,—The amount of illness and suffering produced by inflammation of the uterine appendages is out of all proportion to the mortality. The symptoms vary infinitely in severity. In a considerable number of women the physical signs of these affections are found, so to say, accidentally and no pain or disturbance of function is present that can be attributed to the disease. In another large group of cases the patients apply for the treatment of sterility, and it is found that changes, often of considerable extent, are present without any history to indicate the origin of the disease. In many cases this apparently dates from childhood, when the pelvic inflammation may have passed through its acute stage without giving rise to symptoms so severe or localised as to lead to its detection, or with symptoms that are masked by the presence of some graver affection of the lungs or peritoneum. Many of the cases of sterility, however, give a history of some disturbance of function, local pelvic pains or uneasiness, or other suspicious symptoms, dating from about the time of marriage, and in a considerable proportion of these patients signs suggestive of gonococcal infection are present. The onset of the affection may have been acute and more or less severe following upon a labour or abortion. In many cases the disease starts insidiously. A not uncommon history is one of child-bed followed by a red discharge of some duration and by a history of general weakness lasting for several months; afterwards such a patient may consider herself well for months or even years and then from slight or no obvious cause be seized with acute pelvic peritonitis. In such an acute attack the underlying condition of the uterine appendages is often found to be one that has most likely existed for years and that can with great probability be ascribed to the last labour. In many other cases the patient with chronic disease of the appendages, even on the closest cross-examination, can give no indication of the time when the inflammation probably originated.

Chronic and persistent symptoms are usually present in different degrees of severity, often varied by acute exacerbations, which are specially liable to occur at the menstrual periods. Among the symptoms pains of varying character and intensity are most frequent. These may be felt in one or both sides of the lower abdomen, in the sacral region, round the hips, deep in the pelvis, or sometimes shooting down the thigh as far as the knee. Sometimes these pains are only noted at the periods, but generally they are more or less present in the intervals and are especially marked after work or exercise and are relieved by lying down. Dyspareunia is not uncommon. Frequently disturbances of menstruation are present, often due to complicating affections of the uterus but in many cases apparently due to inflammation of the appendages. In the early stages and during acute exacerbations the menstrual discharge is frequently profuse and still more often prolonged, sometimes lasting for many weeks. In the chronic stage (and this is especially true of tuberculous affections) menstruation is often scanty and infrequent. In some cases puberty appears to be delayed in girls whose appendages have become diseased before that epoch and in not a few of the women the menopause takes place early; in many other cases the menopause is postponed. Various discharges are complained of—mucous, serous, and purulent. In some rare cases such a discharge may be profuse at intervals and result from intermittent hydrosalpinx or pyosalpinx. As a rule, it depends on concomitant endometritis, in which condition intermittent profuse discharges are also sometimes observed. The functions of the neighbouring organs, especially of the bladder, are frequently disturbed; pain and frequency of micturition are complained of, especially at the menstrual periods. Pain in defæcation is sometimes observed. Constipation is one of the most frequent symptoms, but occasionally rectal irritation is present and there may be the passage of quantities of clear or inspissated mucus from the bowels.

In most cases, especially when local symptoms are present, disturbances arise in distant organs. These in many cases combine to form the clinical picture of neurasthenia, which often seems to depend on long-continued and repeated pains, especially in women of neurotic or unstable temperament. In many instances, especially where collections of pus have existed for some time, a condition of toxæmia arises. Constipation often appears to have a marked effect in promoting such a condition. The patient becomes prematurely aged, is sallow and anæmic, worn and haggard; there is a certain degree of wasting; the hair is dull, dry, and becomes thin; the muscular tone is flabby; the appetite is capricious or poor and the digestion impaired; the skin is sometimes dry and harsh; and the urine is often diminished in quantity and loaded with urates. In not a few cases in the course of time, sometimes after many years, severe cachexia gradually develops, and the patient eventually dies from exhaustion or as the result of a terminal infection. Operation for pelvic inflammations in women reduced to the cachectic state is attended by considerable risk, and three of the deaths that have followed my operations for pyosalpinx occurred in such patients.

The symptoms, local and general, above described, may persist for years or may clear up after the adoption of appropriate treatment. In a considerable proportion of the cases intercurrent acute attacks of pelvic peritonitis are observed varying in number and severity. In many women one such attack is observed and with proper care is not repeated; in others repeated attacks take place at short intervals, and in still others the latent intervals may be prolonged, even lasting for years. In patients who have suffered severely enough to call for operative treatment a history of repeated acute attacks is very common. They occur in patients affected with non-suppurative conditions as well as in those with suppurative affections, but in the latter class they are more frequent and tend to recur at shorter intervals. Thus of 40 cases classed as catarrhal salpingitis half the patients gave a history of acute attacks, and of these 13, or one-third, had had three or more; of 19 cases of hydrosalpinx, in eight there had been acute attacks, in six of them, or one-third of all the cases, three or more; among 71 cases of pyosalpinx, 56, or about three-fourths, had had acute attacks, many of them having had three or more. In another group of cases the patient gave a history of an acute attack of pelvic peritonitis months or years before being seen and of having never been well since, while about an equal number of women had been affected with chronic, less severe but persistent symptoms from the commencement of the illness.

The acute attacks of pelvic peritonitis so frequently seen in these conditions are common to them and to inflammation of the vermiform appendix, and without making a careful vaginal and rectal examination it is impossible to tell which of the two affections is present. Occasionally, as in three of my patients, one has to deal with a right-sided pyosalpinx with which the inflamed appendix is closely adherent. The total number of cases in which I have found the vermiform appendix involved is 20; in one case it was adherent to a hydrosalpinx, in three to simply inflamed and adherent appendages, and in 16 to suppurating tubes.

Inflammations of the appendages appear in the female sex to take the place to a large extent that is occupied by inflammations of the appendix in the male. Thus in the seven years from 1900 to 1906 inclusive 1086 cases of appendicitis were admitted into the General Hospital, of which only 364—or as nearly as possible one-third—occurred in the female sex.

There are many points of similarity in the pathology and clinical course of the two affections. In both the appendix and the Fallopian tube we have to deal with a hollow muscular tube with narrow lumen lined by mucous membrane. Each communicates with a viscus from which noxious germs are able to obtain access. Under certain conditions such germs may give rise to inflammation of the mucous and other coats of the tube, and as a result the openings may be closed. In this way a collection of irritant material may take place in a closed cavity, where it may give rise to chronic pains or discomfort or may remain entirely latent.

END OF THE FIRST VOLUME FOR 1907.

Printed and Published by the Registered Proprietors at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, July 6th, 1907.

resonant to percussion, being formed of coils of intestine with thickened walls. On vaginal and rectal examination the whole pelvis is roofed in by a firm board-like hardness, from whose middle the vaginal cervix projects downwards. From the cervix the hardness extends in curved surfaces with the concavity downwards to the sides of the pelvis, over which it spreads widely. Through the rectum it is made out that the tissues behind the uterus and above the vagina are hardened, and that the utero-sacral folds are frequently infiltrated and encroach on the lumen of the gut. Behind the upper part of the wall of the vagina a tongue-like process is commonly felt extending downwards in the recto-vaginal septum for some distance, usually ending below in a sharp border. All these changes, as felt by the vagina and rectum, affect the subperitoneal layer of connective tissue—that is to say, they are the signs of a general pelvic cellulitis; but in such cases the further progress of the case shows that the cellulitis is secondary to peritonitis, which constitutes the primary and principal affection.

In many cases an accumulation of serum takes place in the peritoneal cavity in one or several loculi and in this case the principal collection is found, as a rule, in Douglas's pouch. A tender, fixed median lower abdominal swelling may extend as high as the umbilicus; the contour may be fairly well defined; percussion shows that the upper and lateral parts of the tumour are formed by adherent intestine, the lower portion above the pubes being dull. Internal examination shows that the cervix is pushed upwards and forwards behind the pubes and that a rounded tense or yielding elastic swelling extends downwards to a considerably lower level, filling the pelvis and flattening the rectum against the posterior pelvic wall. On abdominal examination the body of the uterus can frequently be felt distinct on the front of the tumour. Apart from the history such a tumour might contain serum, blood, or pus. Blood would be found if the history was that of a ruptured tubal gestation. Under the conditions we are now considering, infection following parturition or abortion, the contents would be serum or pus, and the solution of the question as to which of the two is present has to be sought in the general condition of the patient and in the accompanying physical signs. Where the contents are serous the aspect and general condition of the patient are less grave; the temperature is raised, but is not so constant and not so high as in a case of suppuration; the consistence of the tumour is more elastic, like that of a thin-walled cyst. When suppuration takes place there is, as a rule, a considerable amount of brawny hardness of the surrounding tissues, and the vagina and cervix are œdematous and swollen and dark bluish in colour. A determination of the proportion of leucocytes present in the blood is often of value, although in the early acute cases a leucocytosis of 15,000 or more is frequent even when the exudation is merely serous. In suppuration the blood-count may be no higher at first, but is more persistent or shows a gradual increase.

When septic infection spreads by way of the veins the pelvic signs at first are those of an inflammation of the uterus, which remains tender and enlarged, usually flabby, of the consistence of wash-leather, but later becoming harder. The tissues around the uterus remain soft, but it is often possible to make out small tender cords or nodules formed by the thrombosed veins. As the infection progresses repeated rigors occur with rise of temperature to 103°, 104°, or higher, followed by remission, and these, together with the slightness of the physical signs discovered on a careful pelvic examination, are characteristic.

A late puerperal infection—that is to say, one in which the symptoms first become marked towards the end of the second week or later, is usually due to pelvic cellulitis, to phlebitis, or to upward spread of a gonorrhœal infection.

In the early stages of puerperal infections the indications for treatment are (1) to attempt to limit the entry and spread of the infecting organisms, and (2) to support the patient in her fight against the invasion. The first indication is met by cleansing the uterus and vagina and by keeping the patient absolutely at rest, every movement appearing to favour the spread of organisms further into the tissues. The cleansing should be undertaken without the slightest delay on the first onset of suspicious symptoms and is best effected by the use of the finger to explore the uterus and remove any portions of placenta or membranes that may be left behind, followed by a copious douche of many pints of salt solution or of some mild antiseptic; afterwards the employment twice or three times a day of large vaginal douches of weak lysol or izal solutions is advisable. The use of the curette in these cases is to be deprecated on at least three grounds: it is impossible to tell when the uterus is empty; it is particularly easy in the soft condition of the uterine muscle to cause injury or even perforation; and finally by removing the superficial layers of the endometrium the barriers of fibrin and phagocytes are removed and fresh blood and lymph vessels are opened up for the free entry of germs.

The second indication, to support the patient in the struggle, is to be met by absolute rest to spare her strength; by nourishing diet suitable to the state of the digestive organs to keep up her strength; by quinine in large doses, as a general and nervine tonic, and for its effect in promoting leucocytosis; by sponging the skin with tepid water when the temperature rises above 102°; by attention to the regular evacuation of the bowels; by the administration of alcohol in regulated doses or of hypodermics of strychnine when the use of these drugs is indicated by the state of the pulse, tongue, or skin; and by the relief of pain in the first place by the application of heat to the lower abdomen, and in the second by the administration of belladonna or morphine in the smallest possible effective doses. In addition to these means methods have been devised with the purpose of directly antagonising the germs or neutralising their toxins. Most of them have so far not advanced beyond the experimental stage. Of those to which I have given a fair trial may be mentioned antistreptococcic serum which has occasionally appeared to me to be of service in appropriate cases; and collargol in subcutaneous injections, or by inunction in the form of Credé's ointment, which has produced no obvious effect.

In the early stages of pelvic inflammations surgical methods are indicated when pus has formed, or where a tense elastic swelling is present in Douglas's pouch. In the latter case an incision by knife or scissors is made immediately behind the cervix and extended as far as may be necessary to each side; the lateral portions should be inclined backwards, so as to make the whole incision convex forwards. When the fluid is evacuated the opportunity is taken to ascertain the condition of the appendages by bimanual examination. The cavity is afterwards packed loosely with iodoform gauze, and this is changed every second day. The relief afforded by this method of treatment is often marked and immediate, and the relief of tension appears to have a considerable effect in limiting the degree of the inflammation as well as its spread.

When pus has formed it should be let out at the earliest possible moment by the nearest route. Where it has collected in Douglas's pouch the posterior vaginal incision is used; for abscess in the lateral cellular tissue an incision one inch above and parallel to the middle two-fourths of Poupart's ligament is carried down through the tendon of the external oblique muscle and the transversalis fascia into the subperitoneal space. When the pus collects in a space in the peritoneal cavity above the pelvic brim an incision must be made directly into the abscess cavity. In any case great care has to be taken not to open up the general peritoneal cavity; the pus is removed by swabs or by gentle local irrigation and the cavity freely drained by rubber tubes or gauze.

In the early stages of puerperal infections treatment by more radical operations offers little chance of success. Patients who are gravely septic bear anæsthetics and operations very badly. On the other hand, recovery often takes place without the aid of surgery in cases that appear practically hopeless. Most of the patients operated upon under these conditions die and it is open to doubt whether the few who survive do so because of, or in spite of, the operation. My own experience of removal of the uterine appendages with or without the uterus in six cases of recent puerperal septic and pyæmic conditions has not been such as to encourage me to add to it; in none of the patients was death prevented, while in at least three it was hastened. The main indication is to let out pus and afford drainage; care should be taken not to interfere with the protective barriers set up by nature and especially not to be too vigorous in cleaning away the fibrinous exudations and breaking down the adhesions that shut off the general peritoneal cavity.

GONOCOCCAL PELVIC INFLAMMATIONS.

In rare cases gonorrhœa may lead within two or three weeks of the infection to a virulent and spreading peritonitis. Much more commonly the inflammation only spreads upwards into the tubes and peritoneum after the lapse of

From time to time, from slight causes or for no obvious reason, acute attacks of inflammation are set up, and as a result of such an acute attack the wall of the viscus may perforate and give rise to peritonitis. In appendicitis the intercurrent acute attacks appear to be much more apt to become diffuse or spreading—a tendency that is explained by the fact that the micro-organisms implicated differ from those usually found in cases of pyosalpinx. In appendicitis the germ most frequently found is the bacterium coli commune, while in cases of pyosalpinx this organism is not common, the condition depending in the great majority of cases on the gonococcus, streptococcus pyogenes, or on various saprophytic organisms. All these germs are relatively of lower virulence than the bacterium coli with the exception of the streptococcus, which as a rule soon loses its virulence and dies out in a closed cavity.

A possible source of infection of the Fallopian tube from the vermiform appendix or *vice versâ* is by way of the connective tissue in the appendiculo-ovarian ligament, but by far most frequently extension of infection from one to the other takes place by simple contact. In all my operative cases the appendix had become adherent in exactly the same manner as any other viscus that happened to be in contact with the tube and ovary at the time of acute inflammation. On examination afterwards the affection of the appendix has usually been limited to its peritoneal coat, and where the change has been more advanced the peritoneum and muscular coats have always been most affected, the mucous membrane being normal and the lumen empty. In some cases, however, the tube or ovary becomes affected secondarily to an appendicitis, as was shown by the case of a girl of 12 in the post-mortem room, where a gangrenous appendicitis had set up an abscess in the right adherent ovary.

The intercurrent attacks of acute pelvic peritonitis are frequently called "obstruction of the bowels," "inflammation of the bowels or of the bladder," sometimes "typhoid," and much too frequently of late years "appendicitis." The onset is most likely to take place at a catamenial period, but very frequently occurs in the interval between two periods. It is occasionally perfectly sudden, usually as the result of an accident, such as a fall, or a blow, or of over-exertion in straining or lifting; in many such cases the onset is accompanied by hæmorrhages into the pyosalpinx itself or into the ovary. Much more commonly the onset is not sudden but acute, pain in one or both sides of the lower abdomen gradually increasing in the course of a few hours or of a day or two until the patient is obliged to give up work and go to bed. The pain is often attended by a feeling of nausea or retching, and sometimes it causes actual vomiting or occasionally a feeling of faintness. Not infrequently the beginning of the attack is marked by shivering, or even in rare cases by a distinct rigor. The temperature rises to 102° or 103°, or even higher; the pulse becomes more frequent, often out of all proportion to the rise of temperature. Pain and frequency of micturition are commonly among the most serious complaints. Much less often there is rectal irritation, amounting sometimes to severe tenesmus and accompanied by the passage of copious mucus, occasionally mixed with blood. The aspect of the woman soon alters, especially if she persists in getting about; her features become drawn, her countenance pale, and she soon presents the appearance of a patient seriously ill. In many such cases a remarkable improvement in the symptoms and in the aspect of the patient follows rest in bed, even for a day or two. According to the severity of the symptoms cases are divided into simple acute pelvic peritonitis and septic peritonitis. In the former cases the symptoms—pain, elevation of temperature, increase in the pulse-rate, and sickness—are all moderate in degree and promptly relieved by rest in bed. In the latter the aspect of the patient is bad, the pulse is rapid, there is more or less frequent vomiting, the abdomen becomes distended, and the patient is sleepless and unable to take nourishment.

DIAGNOSIS.

The symptoms of which the patient complains serve merely to indicate the necessity for careful objective examination, on the result of which depends the diagnosis and consequently the treatment proper to be pursued. The examination involves a complete investigation in the first place of the condition of the pelvic organs and tissues, and in the body, next of the condition and functions of the rest of the body. The pelvic exploration includes inspection, palpation, and percussion of the lower abdomen; vulvar and vaginal examination by inspection and palpation and sometimes by the use of the sound and speculum; rectal examination; and abdominal palpation with the help of a finger in the vagina and one in the rectum. In a case of pelvic inflammation in the female none of these methods should be neglected, and by their means it is generally possible to obtain fairly accurate information as to the nature of the condition with which we have to deal. Since the indications for treatment depend on the results of examination it will be convenient to consider the two subjects together.

PUERPERAL PELVIC INFLAMMATION.

The puerperal state has been seen to be the commonest occasion for the origin of pelvic inflammations generally; of 260 cases, 176, or nearly two out of three, could with great probability be referred to the last pregnancy, ending either at full term or in abortion. The symptoms of infection may arise early, in the first two or three days, or later, in the second or third week. Frequently the symptoms are only observed when the patient begins to get up towards the end of the second week, but it is probable that more careful observation at an earlier date would show in the great majority even of these cases some indication of abnormality in temperature, pulse, lochia, or other symptoms. The worst cases are those in which infection takes place during or soon after delivery: a chill or rigor with marked rise of temperature and the general symptoms of fever occur as a rule within 48 hours, attended sometimes by pain and usually by tenderness to pressure in the lower abdomen. The lochia sometimes dry up; where the infection is due to saprophytes the discharges become foul; in the worst cases of streptococcal infection they may be normal in naked-eye appearance and amount, as well as in odour. On pelvic examination within the first two or three days after infection the vagina is hot and may be dry, the uterus is tender and flabby, and there is a general feeling of bogginess of the tissues; around the uterus nothing definite can be made out. The patient may die from acute toxæmia without developing more distinct local signs. At the beginning of the infection a leucocyte count is of importance in prognosis, a high percentage being of good omen and a low one unfavourable. The early formation of a distinct inflammatory exudation is a favourable sign, as indicating the local resisting power of the tissues.

If the patient survives the signs alter in the course of a few days as the local barriers to the spread of infection begin to be formed. From the sero-fibrinous exudation at first thrown out a deposit of fibrin takes place; the serum drains away or may accumulate in the peritoneal cavity, and especially in Douglas's pouch. The tissues in which fibrin is deposited are brawny and of board-like hardness; and from the shape and position of such a brawny tumour an inference can be drawn as to the part affected. In cellulitis the portion of the cellular tissue most commonly involved is that at the base of the broad ligament on one side, and here a more or less conical tumour forms with its truncated apex at the isthmus of the uterus, which is sometimes pushed towards the opposite side, and with its outer end or base spreading widely over the side and posterior wall of the pelvis, as well as upwards over the brim into the iliac fossa; the vaginal fornix is obliterated, the vaginal wall pushed downwards by the lower surface of the tumour, which is usually concave, and extends low down on the side of the pelvis. Through the rectum the brawny hardness may be felt extending backwards on the pelvic wall as far as the middle line, involving the utero-sacral fold and coming close to the side of the gut. Frequently at this stage the hardness extends to some extent towards the other side behind and in front of the supravaginal cervix, and the swelling may open up the layers of the broad ligament, the uterus being apparently embedded in the side of the tumour. The upper abdominal surface of the swelling is usually well defined but tender.

If the peritoneum is the part affected the fibrinous deposit takes place on the surface of the serous membrane and in the connective tissue immediately below it as well as on the surface and in the walls of the organs in contact with it, especially of the large and small intestine and omentum. When the peritonitis extends above the brim of the pelvis a fixed tender hardness is felt in the lower abdomen, the upper border of which is not well defined, partly by reason of the accompanying distension and muscular resistance, and partly because the upper border of the indurated tissues gradually shades off. The upper part of such a swelling is before admission the patient was at work, in the course of which she made a sudden turning movement which appeared to cause something to give way in the lower abdomen. On admission she was gravely ill, and was constantly vomiting; the temperature was 101° F., the pulse was 132, and the leucocyte count was 28,000. A double tumour was present in the posterior part of the pelvis; lower abdominal distension and rigidity prevented the determination of the upper border of the swelling. Eight days later the patient was very much better, the temperature varying from 98° to 101°, the pulse being 100, and the leucocytes numbering 17,000. The mass was now well defined, very much larger, and extended upwards to the umbilicus. 14 days later the swelling had nearly subsided into the pelvis, the temperature and pulse were normal, and the leucocyte count was 11,500. A diagnosis of double pyosalpinx was made and five weeks after admission the abdominal radical operation was performed, both tubes being found distended with pus. A small collection of pus was also present in a pouch among the intestines at a little distance above the pelvic brim; this pus and that from the tube both gave pure cultures of streptococcus pyogenes. The patient made a slow but otherwise satisfactory recovery and was discharged to a convalescent home six weeks after the operation.

Treatment during the subsidence of acute symptoms has to be directed towards aiding the patient to get rid of the débris. For this purpose the most important means is prolonged rest, until the acute symptoms have completely passed off. If arrangements can be made for much of this rest to be taken in the open air the patient convalesces with greater rapidity. Nourishing diet suited to the digestive powers, careful attention to the excretions, and the administration of tonics are the other important points in the general management of such a case. Means intended to promote absorption comprise the local use of copious hot vaginal douches, vaginal tampons saturated with glycerine, glycerine and ichthyol, with solutions of iodide of potassium and vinum opii, or other agents. The application of iodine or of repeated flying blisters to the lower abdomen is of less use. In many cases the local application of heat to the pelvis by means of an electric bath has appeared to me to be of decided service. In the more chronic cases the continuous administration of small doses of mercury and iodide of potassium, as recommended by Professor J. W. Taylor, deserves a trial. When the acute symptoms have completely subsided gradually increasing exercise, especially driving and walking, is of service and a change of air and scene is indicated. For some months it is advisable for the patient as far as possible to keep her bed during the menstrual periods and at any rate to be careful to avoid at this time any form of over-exertion, whether at work or exercise, and particularly to avoid "catching cold."

At any time during the months succeeding the acute attack the question of operation may arise and I find that among my operations 11 non-suppurative cases out of 83 and 29 suppurative out of 152 were operated upon within a year after labour or abortion. Among the suppurating cases pus in the ovary and pelvic abscess formed the most frequent conditions calling for early operation, 12 cases of pelvic abscess out of a total of 41, and 12 of suppurating ovarian out of a total of 31 being operated upon in these circumstances. The principal indications for early operation are found sometimes in the persistence of severe symptoms such as fever, pains, and general illness, and at others in the occurrence of repeated acute attacks of pelvic peritonitis following each other at short intervals. In such cases it is important to wait whenever possible until there is a strong probability that the pus has become sterile, a point to which I shall return later.

CHRONIC PELVIC INFLAMMATION.

In the chronic stage of pelvic inflammations, when active changes have long since ceased, the amount of local change varies enormously. In a large number of cases the only physical signs are those of adhesions, as shown by the immobility of organs which in normal circumstances are moveable. The uterus is not infrequently bound down in retroversion by adhesions left after pelvic peritonitis, the adhesions being found most dense and abundant about the body of the uterus itself, the ends of the Fallopian tubes sometimes remaining free in cases where infection has spread through the wall of the uterus into the peritoneal cavity. Where the spread has been by way of the tubes the adhesions are most abundant and firm in the neighbourhood of the peritoneal ostium. The adherent ovary does not slip from between the fingers in bimanual examination, so that it is particularly easy to palpate. The position of such an adherent ovary varies; sometimes it is plastered on to the side of the pelvis, a considerable interval intervening between it and the side of the uterus. More often it is adherent to the back of the broad ligament at a lower level than natural, often close to the side of the uterus.

In many cases the signs of an old inflammation are more marked and are to be found in matting together of the appendages to form a characteristic swelling, which is sometimes called the tubo-ovarian tumour. This tumour comprises the thickened Fallopian tube, ovary, and broad ligament, all of them adherent to each other, and the mass occasionally also adherent to other structures, especially the omentum, coils of intestine, and uterus. A vivid imagination may sometimes trace the thickened tube in its course round the ovary, which forms a small firm mass in the middle and lower part of the lump. Where there are adhesions to intestine the apparent size of the tumour often varies remarkably at different times, being larger when the adherent coils are distended and smaller when care has been taken to empty them before examination. The shape of the tubo-ovarian tumour is uneven on the surface, on the whole rounded or oval; the consistence characteristically varies from part to part, the ovary forming a firm part of the tumour, the tube usually feeling less firmly solid, and any cyst that may be present in the ovary or in connexion with the layers of broad ligament forming a softer portion. The mass is tethered more or less firmly by adhesions; there is tenderness, usually not very severe. In two-thirds or more of the cases the affection is bilateral, though usually the changes found differ on the two sides. A smaller similar tumour may be present on the opposite side, or there may be merely the signs of an adherent ovary, or the uterus may be drawn over and adherent to the opposite side in the absence of any obvious swelling in that situation. Examination by the rectum enables the size, shape, and consistence of the tumour to be determined more accurately and its relation to the back of the broad ligament and to the uterus to be more clearly defined.

In other cases the tube is distended into a sac containing serum or pus. Hydrosalpinx forms a thin-walled cystic swelling; pyosalpinx a hard, thick-walled tumour. In some of the larger cases of hydrosalpinx the tumour forms a considerable swelling rising out of the pelvis into the lower abdomen, where it forms a more or less rounded well-defined tumour extending as high as, or even higher than, the umbilicus, not tender, and in this situation often showing a certain amount of mobility. Bimanual examination shows that the uterus in the great majority of cases is on the front of the tumour, though occasionally it is found retroverted with the tumour lying above and in front. In the smaller cases the distended tube, together with the ovary, forms a mass varying in consistence from part to part, the ovary lying below in the midst of the tumour and feeling firm, while the dilated tube, softer and more yielding, curves round it. Where the hydrosalpinx has attained a greater size the outer end forms by far the larger portion and it may sometimes be made out that the inner end attached to the cornu of the uterus is thickened to the size of a finger or so and characteristically convoluted. The outer and lower part of the tumour is practically always densely adherent to the side of the pelvis or the back of the broad ligament, as is evidenced by lack of mobility. In the largest cases and in those where the uterus is retroverted the relation of the tumour to the uterine cornu is often difficult or even impossible of recognition. In a small number of cases a hydrosalpinx opens up the layers of the broad ligament and extends downwards towards the pelvic floor; in such cases the uterus is pushed forward and towards the opposite side and the physical signs are those of an intra-ligamentary ovarian cyst. In most cases of distended tube the appendages of both sides are affected, but as a rule not symmetrically. With a hydrosalpinx of fair size there may be found a smaller hydrosalpinx on the opposite side, or merely the signs of an adherent ovary, or of an ovary and tube thickened and matted together, or the uterus may be drawn over and adherent to the opposite side in the absence of any obvious swelling in that situation. A hydrosalpinx is not tender to pressure. Any tenderness that may be present is due either to the condition of the ovary or to that of the pelvic peritoneum.

months, or sometimes even years. The relation of the infection to pregnancy and the puerperium is of peculiar interest not only from the scientific point of view but from that of the practising obstetrician. In married women a severe vulvo-vaginal and cervical gonorrhœa is not very common; the great majority of infections are due to marriage with men in whom gonorrhœa of more or less ancient date has never thoroughly healed. Some practitioners there are who hold the opinion that gonorrhœa once acquired never entirely clears up, but this is undoubtedly a gross over-statement. In the circumstances attending marriage a gleet, however slight, is apt to become more virulent, and gonococci become implanted, usually in the cervix and in the urethra; the resulting catarrhal inflammations are frequently slight and attended by a trifling sense of local irritation, white or yellowish discharge, and some heat and frequency in micturition, all which symptoms may pass off in the course of a few weeks. If the patient conceives the discharge and local irritation may become more marked, but are commonly supposed to be due to the pregnancy. When delivery takes place either in the earlier months or at full term the gonococci find conditions favourable for their growth and development, and extension upwards into the body of the uterus and thence into the Fallopian tubes and peritoneal cavity is particularly apt to occur. This upward spread takes place gradually; at first the endometrium is invaded, as is shown by the lochia becoming more profuse and continuing to be bloody for a longer time than usual and perhaps by a little local uneasiness, especially in connexion with the bladder; after a few days the tubes become involved, but this only gives rise to a little uneasiness or dull aching pains in the sides of the lower abdomen; finally, the infection spreads into the peritoneal cavity and then, for the first time, the local pains become severe and the temperature and pulse markedly raised. The apparent beginning of a gonorrhœal inflammation in the second or third week or even later after delivery is thus explained, the upward extension taking a certain time to develop. The physical examination of such a case before the peritoneum is invaded may show thickening in the course of the Fallopian tube, more easily observed in the inner part near where it joins the cornu of the uterus. As a rule, however, attention is not called to the pelvis until the peritoneum is involved and then the signs of a localised peritonitis are present with an amount of serous effusion into the cavity and of induration of the surrounding tissues varying with the severity of the inflammation. In some cases puerperal gonorrhœal infection sets in suddenly with fulminating symptoms of peritonitis, but even in these cases the symptoms in the course of two or three days frequently undergo a remarkable change for the better at the same time as the local signs become those of a limited pelvic peritonitis.

The diagnosis of the gonorrhœal nature of a case of puerperal infection, as of gonorrhœa generally, depends upon the recognition of gonococci in the discharges from some of the infected surfaces; search has to be made in the secretions of the urethra and cervix, and in the lochia. The lochia, at first bloody, later becomes purulent or mucopurulent, often of greenish colour. Other indications may be present. If pressure on the urethra from above downwards discloses the presence of opaque secretion, that is in itself suspicious, and the suspicion becomes more marked if Skene's ducts contain such secretion, even in minute quantity; sometimes these ducts are felt to be thickened, hard, and tender, and occasionally the whole urethral wall is thickened and indurated. Much less commonly the ducts of Bartholin's glands are inflamed and contain purulent secretion which can be pressed from them; or the orifices of the ducts are surrounded by a red areola; or the glands themselves are hard, tender, and enlarged by inflammation. In the presence of any of these signs in connexion with the urethra or Bartholin's gland a presumption of infection by the gonococcus is raised, but remains merely a presumption, since the same changes may be due, though rarely, to other causes. The affection of the baby by purulent ophthalmia, which in the great majority of cases is due to infection by the gonococcus, may be an important indication of the nature of the case. The late onset of the infection in the puerperium and the condition of the discharges are also suggestive but the diagnosis can only be made certain by the discovery of the gonococcus. In the early stages of the disease this is easy, the organisms being present in enormous numbers, but soon the gonococcus becomes crowded out by the growth of other germs, and after a lapse of a few weeks its detection becomes difficult or even impossible.

The treatment of a case of acute gonorrhœal peritonitis is conducted on the usual principles, with the addition of attention to the inflammation of the accessible portions of the tract, the vulva, vagina, and cervix. Where there is severe acute inflammation of this part of the tract absolute rest in bed is indicated, together with the use of bland and unirritating douches. Even when the affection has not penetrated to the tubes or peritoneum it is best in the acute stage of gonorrhœa not to attempt any heroic measures to cut the affection short, such treatment rendering the upward spread of the disease more likely. When the acute signs subside applications of 2 or 3 per cent. solution of nitrate of silver may be made with advantage to the affected surfaces.

SUBACUTE PELVIC INFLAMMATION.

When an acute attack of puerperal, gonorrhœal, or other inflammation begins to subside nature undertakes the task of clearing away the inflammatory exudation and other débris resulting from the struggle. In equal steps with the improvement in the local signs and general condition of the patient absorption of the more recent exudations goes on and gradually the signs of peritonitis, with its accompanying cellulitis, are replaced by those proper to the underlying condition of the tubes or ovaries, the uterus returning more or less completely to its natural position. Remains of hard, brawny exudations may persist for some time, most commonly on the side of the pelvis, on which in many cases of pyosalpinx a hard, uneven elevation is felt, widely spreading over the surface. Absorption of this exudation and of the collections of serous fluid in the peritoneal cavity takes place with varying rapidity; sometimes a tumour of considerable size will disappear in the course of two or three weeks, in other cases the swelling subsides to some extent but remains considerable for many months, and this appears to depend commonly on collections of pus in the ovary or tube.

The amount of recovery after an attack of severe inflammation is often surprising and may be so complete that conception takes place promptly and the patient may even pass through the resulting pregnancy with comparatively little disturbance. In a very large proportion of the cases, however, recovery is only partial, the organs and pelvic peritoneum remaining in a state of subacute or chronic inflammation, and the patient suffering more or less severely from the various chronic symptoms that have already been detailed, or frequently experiencing repeated acute attacks. In some cases these attacks gradually decrease in severity and after the second or third there is no recurrence. Such a course has appeared to me to be more frequent after infection by the pyogenic organisms. A typical case of this kind was the following:—

The patient, aged 25 years, was admitted to the General Hospital, Birmingham, on the eighth day after labour with a retained placenta and pelvic abscess; the leucocyte count was 24,000, the temperature was 101°F., and the pulse was 116. Pus giving a pure culture of streptococcus pyogenes was evacuated by a posterior vaginal incision and the patient was discharged a month later. Three months after the labour she was readmitted with an acute attack of peritonitis. There was a mass chiefly in the right posterior quarter of the pelvis, the temperature was 100·8°, the blood count was 9000, and the pulse was 112. The attack subsided promptly with rest in bed. Three months later she was admitted with a third attack of acute pelvic peritonitis attended by considerable exudation behind the uterus. The general appearance was good, the temperature was 98·4°, the pulse was 76, and the leucocyte count was 11,700. Through a posterior vaginal incision serous fluid was let out, which gave a feeble growth of staphylococcus albus. Bimanual examination with two fingers through the incision showed that there was a small swelling about each set of appendages, probably due to matting. The patient made a good recovery and has remained well since. Here the streptococci died out completely in less than six months, and the successive attacks of acute pelvic peritonitis gradually diminished in severity.

In other cases the acute symptoms soon subside, the patient returning to work and remaining fairly well, even for long intervals, and then on slight occasion developing a dangerous illness. Such a case occurred in a woman, aged 22 years, who had had a six months' miscarriage 15 months before admission and had made a fair recovery. Three days is set up, the weak general condition of the patient, and especially of her nervous system, magnifying any pains that are present, and the local disturbance in its turn causing deterioration of the general strength. Such patients are frequently of a neurotic stock and included among them are many highly intelligent young women, sometimes tall and thin, but often below the average size, and slim in proportion. Patients in the same group frequently have a floating kidney and occasionally suffer considerable inconvenience from that cause. They are generally women in the twenties or early thirties and I have not been able to discover what becomes of their complaints after the age of 40. In them surgical treatment is usually of little benefit. The disuse into which the term chronic ovaritis has fallen has made it more and more difficult to label the cases, but has probably proved a gain to the patients. The condition appears to be due primarily to neglect of the elements of hygiene, to the want of proper exercise and fresh air, and to improper feeding. Often the teeth are defective and, as a result of all these causes, the functions of digestion and assimilation become defective.

In another group of patients with signs of salpingo-ovaritis the complaint is merely that of sterility. Sometimes in these cases there is a temptation to suggest operation with a view to opening up the tubes. Before deciding upon such a course it is necessary to make sure that no trace of gleet remains in the cervix or urethra and that there is none in the husband, otherwise the operation can hardly prove other than a failure. In the treatment of these cases there is no question of the ordinary routine treatment for sterility, that of dilatation of the cervix, and it is well to bear in mind that whenever there are physical signs, however slight, of old disease of the appendages dilatation of the cervix is attended by very considerable risk.

In other cases in which there are physical signs of old inflammation of the appendages, chronic complaints of pain of moderate severity, of dysmenorrhœa, or of menorrhagia, or leucorrhœa are made. In these cases the usual treatment of the symptoms by medical means generally suffices but in ordering and carrying out such treatment it has to be borne in mind that a fresh acute attack may easily be set up. Surgical procedures which are usually of minor importance, such, for instance, as dilatation or curetting, and strong applications to the interior of the uterus, are generally to be avoided and where considered necessary should be undertaken with even more than the usual precautions.

In patients who make their appearance for the first time in an intercurrent acute attack it is often necessary to decide whether operation should be recommended at once or whether medical treatment should be continued. Occasionally it may be necessary to operate at the height of an acute attack to endeavour to save the patient from imminent death. Usually the urgency is less and experience has proved that where it is possible to postpone operation success is more easily and safely attained when the operation is performed at the end of an acute attack. It would appear that the patient's blood and tissues become protected, presumably by antibodies of various kinds, which are heaped up during the course of an acute attack, and that the immunity thus acquired diminishes with some rapidity after the acute attack has completely passed off. The decision to make it a general principle that operation should be undertaken after the patient has had a certain number—one, two, or more—of acute attacks is not easy in these cases as in appendicitis. In the latter case we are dealing with an organ that is probably of no use to the economy, while in the former we have to do with organs which, in addition to their own proper functions, exercise an important influence on the whole of the body, so that it is desirable whenever possible to preserve them. The decision to operate in a patient who suffers from acute attacks must depend on the social position of the patient as well as on the number and severity of attacks. Where the severe attacks follow each other at short intervals and there are marked signs of changes in the appendages operation should be undertaken. Where the attacks occur at increasing intervals and become gradually less severe, and where the physical signs and symptoms in the intervals do not point to the presence of pus, medical treatment should be patiently persisted in.

When operation has been decided upon in a case of pelvic inflammation it is necessary to decide by what route, vaginal or abdominal, the operation should be done. Both routes have their special advocates who prefer one or the other in every case. Each, however, has its own sphere. Operations through the vagina are most useful in certain of the less severe cases in which intervention is indicated. Where the tube and ovary are enlarged moderately and adherent chiefly to the uterus, so that they move fairly freely together, then operation through the vagina, preferably through the anterior fornix, is advantageous; but where the appendages are adherent firmly to the side of the pelvis, where there are wide-spread adhesions, or where the uterus cannot be brought down to the vulva, the abdominal method is by far preferable.

The numbers in brackets signify deaths following operation.
* Excluding 17 with pyosalpinx.
† Excluding 12 with pyosalpinx.

In 41 of my cases operations of various kinds have been carried out through the vagina. In 13 of these an incision for the evacuation of pus has been made, usually through the posterior fornix; two of these cases died, both patients being in a gravely septic condition at the time of operation. In several other cases a posterior vaginal incision was made by myself or others and at a subsequent date when the affection of the appendages demanded it a second and more radical operation was performed. In 16 cases various conservative procedures were undertaken through the vagina, including salpingostomy, breaking down adhesions, ignipuncture, and resection of the ovary. In eight cases one set of appendages was removed by this route for inflammatory affections. In one case of double hydrosalpinx and in three of double pyosalpinx, all complicated by prolapse of the uterus, the vaginal radical operation was performed.

In 21 of the vaginal cases operation was undertaken for various non-suppurative conditions and for the same group of affections, including hydrosalpinx, 73 of my operations have been performed by the abdominal route. The procedures here include the removal of one set of appendages in 30 instances; of both sets in 14; various conservative operations in 22; and the abdominal radical operation in seven, including four cases of large and very adherent hydrosalpinx. In the total number of 94 operations for non-suppurative conditions there have been three deaths. One of these was due to pulmonary embolism on the eighth day after operation, the patient with normal temperature and

Pyosalpinx forms a hard, uneven, and immoveable tumour; the hardness depends on inflammatory thickening of the walls of the tube and of the broad ligament and pelvic peritoneum as well as on the incorporated ovary. The consistence often varies at different parts; the pus tends to collect more in the outer ampullary portion of the tube, in which position there is accordingly often a softer and more yielding part. The mass is usually tender, though in chronic cases this sign may be entirely absent. The shape of the tumour is irregular and uneven. Occasionally it can be made out that there is a large, irregular, rounded tumour with a thickened firm prolongation uniting it to the cornu of the uterus. In the larger cases the shape is sometimes elongated and curved like that of a sausage or banana, and in the same cases the consistence, owing to the relative thinness of the walls and abundance of fluid contents, is frequently softer and more cystic, sometimes resembling that of a hydrosalpinx.

The physical signs are bilateral in more than two-thirds of the cases, but as in the case of hydrosalpinx, so here, the signs are usually not symmetrical. Where two large tumours are present they frequently come into close contact in the middle line, but it is generally possible to make out that a large mass filling up the posterior portion of the pelvis is double by feeling an antero-posterior groove on the lower surface, either through the vagina or much more easily through the rectum.

In the intercurrent acute attacks of pelvic peritonitis great variety in position is found in the physical signs, and these vary according as the peritoneum with its adjacent connective tissue is infiltrated and hardened (fibrinous peritonitis) or as collections of fluid form in the peritoneal cavity (serous peritonitis). The upper portion of the tumour is formed by adherent intestines and omentum and consequently the upper limit feels ill defined on bimanual examination. As absorption takes place the induration diminishes irregularly and gradually the physical signs of enlargement of one or both sets of appendages become marked. The induration tends to remain longest as a rule on the outer and posterior pelvic wall where it may often be felt as an uneven, broadly adherent firm plate between the outer end of a pyosalpinx and the pelvic wall.

In cases of pelvic inflammation, no matter to what germ the disease may be attributed, it is of the greatest importance in deciding upon treatment to be able to diagnose whether pus has been formed. Help in making the diagnosis may be sought in the physical signs. In the early stages when, in the middle of hard, board-like exudation, patches of softening make their appearance along with the general symptoms of suppuration, the presence of pus and its location become evident. In the presence of an acute intercurrent attack of pelvic peritonitis it is impossible to diagnose the presence of pus until the acute symptoms have passed off, and absorption of the recent inflammatory products has taken place. Then, if the case be one of pyosalpinx or of suppuration in the ovary, the resulting tumour is hard and nodular and usually firmly fixed by adhesion to the wall of the pelvis. If no pus be present the consistence is less dense, and frequently thin-walled cystic portions may be made out, due usually to small cysts in the ovary or to hydrosalpinx. Much help is afforded by a leucocyte count in many cases, but this requires to be taken into consideration along with all the other symptoms and physical signs. The leucocyte count is merely a link in the chain of evidence, a strong one no doubt, but still only a link. In acute intercurrent attacks of pelvic peritonitis the blood count is commonly found to be raised, being often 15,000 or more, even in non-suppurative cases. As the attack passes off the blood count in these cases rapidly falls to normal. In suppurative cases, on the other hand, the count is sometimes observed to increase or to remain for a considerable time above normal. The location of the pus has a marked influence on leucocytosis, collections in the peritoneal cavity as a rule giving a higher and more persistent blood count than collections in closed cavities, as, for instance, in a pyosalpinx or suppurating ovary. The particular micro-organism present has also an influence. In attacks of acute gonorrhœal salpingitis the blood count is raised only to a moderate degree, usually not more than 14,000 or 15,000. In infection by the staphylococcus and streptococcus the blood count is frequently much higher. In tuberculous affections the number of leucocytes does not exceed, and often falls below, the normal average; when it remains persistently high it points to the occurrence of a secondary infection by pyogenic or saprophytic organisms. In a doubtful case repeated estimation of the leucocytes is important and frequently enables us to form a correct opinion as to the presence of pus.

When pus has formed it is of great advantage to know whether it still contains living organisms or not. Where these are still present it is better, whenever possible, to postpone radical operation, and to content ourselves with opening and draining abscess cavities in the peritoneum or cellular tissue. Pathogenic and saprophytic germs in closed sacs usually quickly die out but the time taken in the process varies very greatly. Nine months has been suggested as the time after which one may reckon with reasonable certainty on pus having lost its virulence, but in many cases the germs disappear in a considerably shorter time than this. In some cases, on the other hand, germs live for much longer, and in one of the cases above related living streptococci were found in a pyosalpinx that ruptured 15 months after its origin in parturition.

The presence or absence of fever is no certain indication, though it has a certain importance; in the majority of cases in which fever is persistent germ-containing pus is present and therefore it is better to wait, unless there are symptoms of urgency. A high leucocyte count usually means the presence of virulent pus and where present it is also better to put off operation. In many cases, however, leucocytosis is present in cases of suppuration where the pus is sterile.

The exploring needle may prove useful in obtaining pus from cases of pyosalpinx for the purposes of bacteriological examination and when carefully used with aseptic precautions the small puncture necessary is not likely to give rise to trouble. The puncture should be made through the vaginal fornix after careful bimanual examination to determine the probable situation of the pus.

In chronic cases of pelvic inflammation it is frequently impossible to determine the germs which caused the condition, these having long ago died out. Where foul-smelling pus is present the cause has been either some of the putrefactive organisms, or the bacterium coli commune, but even here the original cause of infection is often uncertain, because an old collection of pus may become secondarily infected by the bacterium coli penetrating through the wall of an adherent coil of intestine. This seems to be a not infrequent occurrence in tuberculous pyosalpinx, as was proved in a recent case of my own, and as I believe happened in at least two other instances. Where the pus in a pyosalpinx is sterile, and has no disagreeable smell, it is often impossible to tell whether it owes its origin to the gonococcus, or to the streptococcus, or other pyogenic organisms. In many cases, however, even in the most chronic class, it is possible to obtain some assurance of the nature of the case. The gonococcus has the peculiarity of affecting many different parts of the genital tract, and the inflammations caused by it tend to persist indefinitely; frequently, therefore, evidence can be found in the state of the urethra, vulva, vagina, and cervix, which, while stopping short of actual proof, nevertheless affords a strong presumption of the origin of the disease in the appendages. Of 94 non-suppurating cases of all kinds, 20 showed fairly conclusive evidence of gonococcal origin; included in these figures were eight cases of hydrosalpinx out of a total of 23. Of 152 suppurative cases 45 were believed on the clinical evidence to be gonococcal. In all probability in a considerable proportion of the remainder the gonococcus had been the effective agent, but had left no trace behind other than the diseased appendages. In a much smaller proportion of cases, two of the non-suppurative and seven of the suppurative, evidence of syphilis was obtained, but it did not appear that this disease had given rise to the changes in the tube and ovary.

The treatment of chronic cases of pelvic inflammation depends partly on the physical signs that are present, and still more upon the course of the affection. In some cases the disease has run its course, leaving only adhesions about the organs, which give rise to no symptoms, the condition of the appendages being discovered, so to speak, accidentally; such cases require no treatment of any kind. In other patients the complaints and symptoms which make up the clinical picture of neurasthenia, are found in patients who have the signs of chronic adhesive pelvic peritonitis or of salpingitis, and it becomes difficult to decide whether active treatment for the condition of the appendages is indicated. Often such patients complain more or less of pains in the genital zone, and of dysmenorrhœa, and a vicious circle

EXPERIMENTAL RESEARCHES ON SPECIFIC THERAPEUTICS.

Delivered at 20, Hanover-square, London, under the auspices of the Royal Institute of Public Health,

BY PROFESSOR PAUL EHRLICH, M.D.,

DIRECTOR OF THE KÖNIGLICHES INSTITUT FÜR EXPERIMENTELLE THERAPIE, FRANKFORT.

LECTURE II.[1]

Delivered on June 10th.

ATREPSY.

GENTLEMEN,—I will give you an example from my researches which will make it clear what I mean by atrepsy, and I will take a fairly simple case—viz., that of the cobra venom. This poison produces in the body a number of very different injuries—e.g., it affects the nervous centres, the subcutaneous tissue, the red blood corpuscles, and the endothelia; each separate and individual effect is the result of a different individual poison. Thus one can prove with absolute certainty that the effect on the nervous tissues is produced by the neurotoxin, that on the blood corpuscles by a hæmolysine, and the inflammatory changes by a special endotheliotoxin. It has been shown that those components of snake venom which attack the red blood corpuscles are present in such a form that by themselves they do not suffice to destroy them.

By following the researches of Flexner and Calmette my former assistant and friend Dr. Kyes has succeeded in throwing some light on these difficult subjects. He proved that the hæmolytic component of the cobra venom is an amboceptor, which, however, differs from the bacteriolytic and opsonic amboceptors by combining not with the complements of the blood but which enters into union with a chemically well-defined substance—lecithin. By shaking cobra venom solutions with a solution of lecithin in chloroform one can show the whole hæmolytic toxin to pass quantitatively into the chloroform part, whilst the watery part has retained the whole of the true poisonous principle—viz., of the neurotoxin. From the chloroform solution one can isolate the active hæmolytic principle by precipitating with ether; it can thus be obtained in the form of a white powder, which in chemical analysis gives figures almost exactly fitting to the formula of a mono-stearyl-lecithin. In this process there has therefore been split off one of the two molecules of fatty acid which can be regained quantitatively from the ether. The substance thus obtained is produced by the union of a *small quantity* of the hæmolytically active part of cobra venom with a relatively large number of lecithin molecules. It is easy to prove that we really have before us here a *chemical compound*, and not the result of an adsorption *similar to that* recently described by Michaelis between rennet and mastix, for it is impossible to split up the substance by *solvents* into two components—namely, mono-stearyl-lecithin and the cobra venom amboceptor, and that should be possible if it were only such a mixture. On the other hand, in conformity with its altered chemical character, the substance has obtained new properties not found in cobra venom. For in the first place it is distinguished from the cobra amboceptor by having become so completely thermostable that solutions of this cobra-lecithide can be boiled for hours without losing a fraction of their efficiency, whilst in similar circumstances the original venom would be rapidly destroyed. A further important property is shown by the fact that cobra-lecithide, even in small quantity, instantaneously and without any incubation, dissolves the erythrocytes, whilst snake venom, even in the presence of lecithin, only produces a similar effect after several hours. The long incubation observed in experiments with the native poison is explained by the fact that the real poisonous body has first to be formed by a synthetic process which in dilute solutions and at ordinary temperatures may naturally require some time for its completion.

Research work has shown that the hæmolytic amboceptors of snake poisons possess different affinities for lecithin. We may conclude that the firmness of union of lecithin in the different blood species is different, being highest in the sheep and the ox, lower in the rabbit, still lower in man, and lowest of all in the guinea-pig. You see here very clearly one of the conditions which are of importance for the definition of atrepsy—namely, that of independence. Lecithin has an affinity for certain constituents of the cell and it also has an affinity for the constituents of the poison; the difference between these two affinities decides whether cobra-lecithin can be formed and hæmolysis can thus be produced. If the affinity of the constituents of the stromata is higher hæmolysis does not take place—i.e., the lecithin is not at the disposal of the cobra-amboceptor.

The atreptic immunity, which results as I stated from certain substances not being at the disposal of the parasites, seems to me to play an important rôle in the study of tumours. I may even say that I first formed the idea of atrepsy as the result of numerous experimental observations upon malignant mice tumours which are of cardinal interest for modern cancer research. I believe that a number of clinical and experimental facts in this sphere of knowledge can only be explained by this hypothesis.

As you know, mice cancers are tumours showing a far-reaching analogy to human cancer, and it would therefore appear most justifiable to regard the experiences gained with them as the solid foundation of an experimental study of the tumour. Besides several analogies, however, the mice tumours show certain special features, chief among which is their mode of formation of metastases. It is most remarkable that the highly virulent carcinomata which have been cultivated in numerous generations very rarely show macroscopically visible metastases, whilst the slowly growing spontaneous tumours relatively more often, though also not very commonly, form large secondary nodules in the lungs. Our interest in this peculiar behaviour must even be increased, since Haaland has shown that microscopical metastases are by no means uncommon, but that they almost always remain below the limit of macroscopical visibility. I endeavoured to solve this problem by making, so to speak, artificial metastases—viz., studying in animals affected with an inoculated tumour the result of a second inoculation. I found the interesting fact, that the effect of the second inoculation was inversely proportional to the energy of growth of the primary tumour. In rapidly growing sarcomata and carcinomata the second inoculation almost always had a negative result; at best, the second tumour remained far inferior in size to the primary one. Only in the very slowly growing chondromata there was no distinct difference in their energy of proliferation. These results agree with the following observation which has been confirmed thousands of times: If, as is regularly done in my institute, the inoculation is carried out by introducing the capillary at the groin and pushing it up as far as the axilla, the greater quantity of inoculated material is deposited at the latter site, whilst only little of it remains at the groin. In the case of the rapidly growing carcinomata and sarcomata the large principal tumours almost always develop in the axilla, whilst a minute nodule is usually found in the groin. In the case of the chrondromata, however, both tumours usually show a fairly equal development. Thus in the latter case the macroscopical appearance somewhat resembles that of an hour-glass, whilst in the former it is more like a balloon with its car attached to it. To my mind, the explanation of this phenomenon is as *follows*: every proliferation depends in the first place on the avidity of the cells for the nutritive substances. Normally there are certain well-defined laws of distribution, which guarantee the normal working of the organic functions. The avidity of the tumour cells is increased compared with that of the body cells. The more energetically a tumour proliferates, the more vehemently does it attract the nutrient substances from the blood. In the case of a rapidly growing tumour it may therefore very easily occur that for such cells which are under very unfavourable conditions of nutrition—e.g., cells inoculated and metastatically carried away—there is an insufficient supply of nutrient substances, and that they therefore either perish from atrepsy or at least are unfavourably influenced in their growth. From this point of view it is pulse-rate having shown no previous symptoms of danger following the operation; the second death was due to anæsthetic gangrenous pneumonia, the pelvic condition as observed at the necropsy being normal and the abdominal incision firmly closed. The third death was caused by peritonitis consequent on an oozing of six or eight ounces of blood from separated adhesions. At least nine of the patients operated upon for non-suppurative conditions of the appendages have subsequently borne children.

---

[1] Lecture I. was published in THE LANCET of June 15th, 1907, p. 1634.

In the worst cases of suppurative affections the choice of operation lies between double oöphorectomy, the abdominal radical operation, and the vaginal radical operation. The vaginal operation has been largely practised by surgeons in France and Germany. In its favour the claims are made that shock is less, that the general peritoneal cavity is not interfered with, that drainage is more direct and efficient, and that there is no abdominal scar to give rise later to ventral hernia. Many surgeons, however, begin the operation by removal of the uterus, and one of the great objections depends upon the possibility of removing a fairly healthy uterus and of afterwards discovering that one set of appendages is still serviceable. A further, still more serious disadvantage is that adhesions, more especially to intestine, are much more difficult to treat by this route and that the repair of a torn viscus is difficult or impossible. The immediate mortality of the vaginal radical operation has not exceeded 5 per cent. in the hands of the best operators, but lacerations and fistulæ, both intestinal and urinary, have been more frequent than when operation is undertaken through the abdomen. Of the abdominal operations removal of the two sets of appendages is the older and has had an extensive trial. The abdominal has, in the first place, the great advantage of enabling us before proceeding to remove any of the organs to make a complete examination and to determine how much it is necessary to do. In many cases the actual condition of the organs is found on opening the abdomen to be decidedly less serious than has appeared from clinical examination, so that it is frequently possible to save one set of appendages. On the other hand, it not infrequently happens that, though signs have been chiefly observed about one set of appendages, the other tube and ovary are so severely damaged as to render their removal advisable. In the next place, adhesions can be separated by the aid of sight as well as of touch, and if intestine, bladder, or ureter is torn the necessary steps for the repair of the injury can be at once undertaken in the most convenient circumstances.

My abdominal operations for suppurative and tuberculous affections include three exploratory incisions with one death, which occurred in a profoundly septic case with perforated pyosalpinx and adhesions so dense that it was impossible to separate them. 36 times the removal of one set of appendages was carried out with one death from septic peritonitis. In 32 cases both sets of appendages were removed with six deaths. In two of the cases the operation was undertaken for tuberculous appendages and was followed by the development of fæcal fistula and death from gradual exhaustion. Of the other four fatal cases, in one the patient was desperately ill with septic peritonitis following the rupture of a pyosalpinx in labour; in a second the woman was wasted and cachectic, apparently as the result of chronic toxæmia; the other two died from septic peritonitis.

In cases of pyosalpinx in the old method of operation a stump of half an inch or so in length of diseased tube was left adherent to the uterine cornu, and from this stump a certain degree of infection was common, giving rise to suppuration of ligatures and consequent sinus formation, or sometimes to fairly extensive and dense peritonitic adhesions. An improvement on this method of treating the pedicle has been made by cutting out the uterine portion of the tube, leaving a wedge-shaped depression that can be easily sutured together. But after the removal of both sets of appendages for suppurative affections the uterus, instead of quietly undergoing atrophy, has often given rise to severe pains and various discharges, so as to render its removal advisable at a later date. In many cases it is found that the uterus is universally adherent, that it is enlarged, and that both cervix and endometrium are in a state of chronic inflammation. Such a condition of affairs is, of course, frequently to be expected since infection usually spreads into the tubes and pelvic peritoneum by way of the uterus. Moreover, it has yet to be proved that the possession of a uterus devoid of appendages, especially when that uterus is more or less diseased, is an advantage to its possessor. The suggestion has been made, based on no evidence, that by leaving the uterus the symptoms of the menopause are modified, and that possibly the uterus provides an internal secretion in the same way as the ovaries are supposed to do. The question of the correct operative treatment of severe affections of both sets of appendages is still unsettled, but the above considerations have induced many surgeons, myself among the number, to undertake the removal of the uterus along with the appendages in cases where these are found to be hopelessly disorganised.

Among my own operations to the end of 1906 are included 53 of the abdominal radical operation for ordinary suppurating affections of the appendages and three for tuberculous disease; five deaths followed—a mortality of nearly 9 per cent. Of the three tuberculous cases the uterus was affected simultaneously with the tubes in two; in the third the tuberculous tubes and left ovary were removed through an anterior vaginal incision, and six years later the tuberculous uterus and right ovary were removed by the abdominal route. The methods of operation employed include supravaginal as well as total abdominal hysterectomy. The supravaginal method was employed in 15 cases, with three deaths. One of the fatal cases occurred in an alcoholic patient; a second in a fat woman with a fibroid weighing three and three-quarter pounds, complicated by a pyosalpinx containing four or five ounces of thick yellow pus; the pyosalpinx had caused constriction of the ureter one and a half inches above the bladder and consequent hydronephrosis. In the third case the patient was ill, dusky, and emaciated, and died from general peritonitis. In the remaining 41 cases the complete operation was done, the cervix being removed along with the rest of the uterus and appendages. Two deaths have followed the operation, a mortality for this method of rather less than 5 per cent. One of the fatal cases occurred in a feeble, emaciated, and cachectic woman, aged 33 years, who had been seized with an acute attack of septic peritonitis three weeks before the operation; the only labour had taken place 12½ years before, and there had been no previous severe attack, though the woman had never been well; death from suppurative peritonitis occurred six days after the operation. The other death occurred in a woman aged 54 years, whose only pregnancy occurred at the age of 23 years; 31 years later abdominal pains began and a tumour was discovered two months before operation; the patient had been wasting for a year. On admission she was desperately ill, with furred tongue, foul breath, pulse 136, and signs of cardiac dilatation. Death occurred nine hours after the removal of a fibroid uterus, together with a large suppurating ovary densely adherent in the pelvis.

The total abdominal operation is in most cases not much more difficult to perform than the supravaginal and presents two great advantages. In the first place a frequent source of subsequent trouble is removed; the blood-supply of the cervical stump is very apt to be interfered with to some extent in the supravaginal method, and the consequent interference with nutrition leads sometimes to a certain amount of necrosis and often permits infection of the cut surfaces and pus formation. In the second place the removal of the cervix permits free drainage to be provided into the vagina where this is considered desirable. On the other hand, the removal of the cervix has no corresponding disadvantages; the only argument for its retention is that it forms part of the pelvic floor, but experience has shown that the pelvic floor is not a whit less capable of supporting the superincumbent viscera after it has been deprived of the cervix.

FOURTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—This congress will be held in Berlin from Sept. 23rd to 29th, under the patronage of Her Majesty the Kaiserin. In order to provide for the entertainment of the numerous ladies, both German and foreign, who are expected to accompany to Berlin the gentlemen who will be engaged in the scientific work of the congress, a ladies' committee has lately been formed under the honorary presidency of H.H. Princess von Bülow, Countess Posadowsky-Wehner, Lady von Studt, and the Lady Mayoress Kirschner of Berlin. Ladies of the committee propose to accompany the visitors to inspect the various establishments for the public welfare, the art galleries, and other interesting sights. Privy Councillor Dr. Ellsberger, president of the local committee of the congress, will act as secretary to the ladies' committee. The address of the secretary-general of the Congress is Eichhornstrasse, 9, Berlin.

phagocytes and by the means of encystment endeavours to make the pathogenic germs harmless and to eliminate them. You see, therefore, that this is a war waged in different fields, but in which to every action there corresponds a reaction. This war is waged in a three-fold manner by variations of affinity, by variations in the poison, and by localisation.

TWO CASES OF INTERMITTENT HYDRONEPHROSIS TREATED BY OPERATION.

BY W. WATSON CHEYNE, C.B., LL.D., F.R.S., F.R.C.S. ENG.,

SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

THE following cases may be of interest as examples of excellent results after operation for intermittent hydronephrosis and as showing a modification in the method of dealing with the upper end of the ureter in some of these cases which is certainly an improvement over what I myself had done in previous similar instances.

CASE 1.—The patient, a married woman, aged 32 years, was admitted to King's College Hospital on Nov. 11th, 1905. She did not give a clear account of her trouble but what she told us practically amounted to this: For the last ten years she had suffered from time to time from attacks of pain in the left loin which had become more frequent of late and were practically continuous for the three weeks preceding admission. Of late she had also had occasional slight pain in the right loin. In these attacks the severity of the pain did not as a rule last longer than 20 minutes and it was accompanied by giddiness and nausea but not by vomiting. The pain was limited to the left loin and did not extend downwards. She had not noticed any variation in the amount of urine passed in connexion with the attacks nor had there ever been any blood in it. On examination both kidneys were freely moveable and somewhat large but they did not appear otherwise abnormal. A skiagram showed no stone. The urine was normal. Consideration of all the points led me to the conclusion that the case was one of intermittent hydronephrosis due either to kinking of the ureter from the mobility of the kidney or to some abnormality about the renal end of the ureter and therefore the following operation was performed on Nov. 17th, 1905.

Operation.—The left kidney was exposed in the loin and brought out through the wound. The kidney was enlarged and there were two cysts on its surface. The pelvis was greatly dilated and was almost as large as the kidney itself; the ureter was about the size of a No. 8 catheter and came off from near the upper end of the dilated pelvis. The result was the production of the valvular condition of the orifice of the ureter which seems to be the commonest cause of intermittent hydronephrosis. An incision was now made into the pelvis of the kidney about half an inch to one side of the ureter and extending upwards around it, and the state of the interior of the pelvis was investigated. It was then found that we had to do with the condition where the opening of the pelvis is placed high up and apparently closes from pressure as the pelvis fills with urine. I then slit the orifice of the ureter and the wall of the pelvis downwards as far as I could without going beyond the connexion between the two. The result did not, however, seem to be satisfactory, and I did not feel at all sure that when healing had taken place the trouble would not be reproduced. I therefore continued the incision in the pelvis of the kidney around the attachment of the ureter and about half an inch from it, or rather more at the upper part and less at the lower. The result was that an oval piece of the pelvis was detached, towards the lower part of which was the orifice of the ureter which had been enlarged by a vertical slit. Two or three fine catgut stitches were then inserted between the edges of the divided ureter and the pelvis, special care being taken as regards the lower angle. A piece of the lower part of the pelvis was now cut away and the oval portion was inserted into this opening by a series of catgut stitches avoiding the mucous membrane. A few additional Lembert's sutures were applied outside. Some of the redundant pelvis at the upper part was cut away and the edges being inverted the pelvis was closed by catgut sutures. The result was that the orifice of the ureter was attached to the lower end of the pelvis of the kidney, that its opening was enlarged and no longer valvular, and that there was a direct flow of urine from the pelvis into the ureter. The kidney was now returned and fixed in the loin in the usual manner and the wound was closed, a drainage-tube being inserted down to the pelvis.

The after progress of the case was uneventful. There was no escape of urine by the tube, which was removed on the third day, and the wound healed by first intention. There was a little blood in the urine for two or three days. The patient was discharged from the hospital on Dec. 30th, 1905, quite well.

CASE 2.—The patient, a man, aged 20 years, a gardener, was admitted on Nov. 11th, 1905. For the last three years he had been subject to attacks of severe pain in the left loin. These attacks had lately become much more frequent and he had had seven during the last two months. Each attack lasted about three days and after a few hours the pain became very severe and was accompanied by vomiting. During the attacks the patient passed but little urine, though afterwards a great quantity was voided. The urine had never contained any blood. The patient knew of no cause for the attacks; jolting did not cause pain nor increase it if it was present. There was no constipation. Neither kidney could be felt. The urine was of specific gravity 1030, acid, and contained no albumin or sugar. On Nov. 12th the patient had had a severe attack of pain in the left loin during the night. He vomited frequently and had to have morphine. The pain was limited to the back and loin and did not radiate down the thigh or towards the testicle. There was marked tenderness in this region. There was a great desire to pass urine but no frequency of micturition. The attack lasted about 12 hours and during that time 18 ounces of urine were passed; it was of specific gravity 1028 and showed an excess of phosphates but was otherwise normal (no note was taken as to the quantity of urine after the attack). There were some rigidity and fulness in the loin but the part was so tender and rigid that it could not be examined thoroughly.

Operation was performed on Dec. 6th. A similar state of matters was found to that described in the former case. The kidney was enlarged, the pelvis was much dilated, and the ureter came off from the upper part of the dilated pelvis. The same procedure was adopted.

After the operation the patient had a good deal of sickness, lasting two or three days. The wound went on well, no urine escaped, the drainage-tube was removed on Dec. 18th, and healing was practically complete by the 26th. On that day, however, the patients in the ward were a good deal excited by the Christmas festivities, and this patient especially was sitting up and twisting about and very active. During one of his sudden movements he felt severe pain in his left side and next day he was tender there and there was some fulness. The temperature went up and during the next four days ranged from 100° to 103° F. and a distinct swelling formed. On Jan. 1st, 1906, an incision was made through the scar and a quantity of turbid urine was evacuated. The fluid contained 1 per cent. urea and a few staphylococci were found in it. A drainage-tube was inserted and for some days a little urine came through it. By Jan. 18th, however, the flow of urine had ceased and the drainage-tube was left out. He left the hospital well on Feb. 2nd.

It is evident that during the patient's violent movements on Dec. 26th some part of the union between the pelvis and the ureter must have given way and leakage had occurred. The opening must, however, have been very small, for once the accumulation of five days had escaped very little urine came by the tube afterwards.

The condition of intermittent hydronephrosis is due to a variety of conditions but the one which I have most commonly come across is that which was present in the two cases described above—viz., the attachment of the ureter too high up on the pelvis, with the result that a valvular opening is formed which tends to become closed when the pelvis is distended. Whether this condition is congenital or acquired I am not prepared to say. It is conceivable that it may be acquired somewhat in the following manner. In all the cases which I have seen the kidney is freely moveable. As the result of that mobility the ureter may become kinked or so curved from time to time that there is a difficulty in the outflow of the urine. The result is that the pelvis becomes distended and as it yields more at the lower part than elsewhere a pouch also quite evident that slowly growing tumours can attain far greater dimensions than rapidly growing ones, since in the former the consumption of nutrient matter, in spite of their size, is less than in the latter, and thus the entire organism is injured to a lesser extent.

I fail to understand how von Dungern can think himself justified in doubting the correctness of my explanation on the ground that hitherto the experimental proof of a permanent increase of cellular avidity by increased nutrition has not been adduced. I have never asserted that we can, by artificial means, permanently raise the cellular avidity. Such a power would obviously involve the possibility of artificial tumour production. There is, therefore, no contradiction—as von Dungern imagines—between my views and the facts that by artificial hyperæmia better nutrition is obtained and that after removal of large parts of the body—e.g., amputation of the thigh—the hypernutrition of the individual is evidenced not by the proliferation of functionating epithelium cells but by increase of the paniculus adiposus. From the fact that the increased avidity causes an increased attraction of nutritive material it does not follow inversely that copious nutrition should increase the avidity. An indirectly injurious effect of more highly avid cells on less avid ones can only then become evident if the body does not possess sufficient nutrient matter to saturate every avidity. What is the origin of the higher avidity of the tumour cells is quite unknown to us, for this question means neither more nor less than the last problem of tumour etiology.

An entirely different significance must be ascribed to the specific growth-producing bodies, for the existence of which we have received irrefutable proof chiefly by the work of Starling. As you may know he observed lactation in non-pregnant females as the result of injecting emulsions of embryones. But, of course, I should never think of asserting, as one might be led to think by von Dungern's explanation of my views, that by hypernutrition a virgin might become a wet-nurse. The specific growth-producing bodies play an important rôle also in other cases and are intimately connected with atreptic immunity. Thus we know that the influenza bacillus cannot do without hæmoglobin for its growth; therefore it is quite easy to cultivate the bacillus directly from the sputum, which almost always contains small quantities of hæmoglobin. But if we do not artificially add hæmoglobin to the subcultures the bacteria very soon die in them. Specific auxiliary growth-substances we must also admit in all those infectious diseases which are characterised by a marked localisation of the poison—even in syphilis.

The case is quite similar in that form of atreptic immunity which follows from my experiments of inoculating rats with mice tumour cells. As you know, hitherto no one has ever succeeded in transferring normal or tumour tissue to animals of a different species. The limits of transplantability coincide with those of bastardisation. The question, however, now arose as to whether the same barriers held good also for our highly virulent tumour material. To that end I employed the rat as the animal phylogenetically most nearly related to the mouse. In fact, if a virulent mouse tumour is inoculated to a rat the result is quite different from all hitherto known true cases of transference of tissue outside a species. For during the first eight days the cells both of carcinomata, sarcomata, and chondromata proliferate in the rat just as in the mouse. During this time tumours arise of the size of an almond to a date, containing numerous mitoses and even microscopically differing in no way from the mouse tumours. After that time, however, the limit of their growth is reached and there now follows gradual resorption, which is concluded after another week or two. If the tumour at its maximum development is transferred to another rat it does not gain any foothold there, whilst if it is re-inoculated to a mouse it again proliferates luxuriantly. It is possible to keep on carrying out this zig-zag inoculation mouse–rat—mouse–rat for any length of time without the slightest check to the energy of proliferation being encountered. The question now arises how it is possible to explain on the basis of these facts the immunity of the rat towards mice tumour cells.

We can *a limine* exclude the existence of a natural immunity by antibodies in the rat, in view of the at first luxuriant proliferation of the tumour. On the other hand, it would be possible to imagine that the resorption of the tumour might be the result of an active immunisation of the rat. That such immunisation ultimately occurs may be proved by the fact that the result of re-inoculating a rat in which a first tumour has been absorbed with a second tumour is always negative. I do not, however, consider it permissible to identify these two manifestations of immunity. For, in the first place, it is highly improbable that during the period of rapid proliferation of the tumour in the rat's organism any considerable absorption of tissue elements should occur. Further, previously to that period a production of antibodies has not been proved. Lastly, since the tumour when re-inoculated to the mouse never shows ever so slight an injury one would have to suppose—with von Dungern—that the anti-substance formed in the rat's organism was activated only by the complements of rats but not of mice. This again has up till now not been proved. A far simpler and more natural explanation of all these phenomena is afforded by my hypothesis of atrepsy. According to this, the mice cells require for their growth not only the ordinary nutritive substances which the rat can also supply to them in ample quantity, but, besides that, some well-defined substance which is present only in the mouse's organism. In the rat then these cells would only be able to go on growing so long as there still remains to them some of the specific growth substance that was introduced with them at the time of inoculation. When it has all been used up growth can only be further stimulated by giving a fresh supply of this substance—e.g., by re-inoculation to the mouse.

Time and again I have laid stress upon the fact that many nutrient substances are not present in the cells in a free state, and that therefore they are not at the disposal of any invader, but that always a struggle is necessary before they can be rendered accessible. In the case of snake venom I have shown that we are dealing with a simple difference between two chemical avidities. In the case of bacteria the affair may be rather more complicated according to the occurrence of either of two possibilities—viz., (1) a direct assimilation in consequence of a higher degree of affinity; or (2) an indirect action by injury to the cell. Supposing, for example, that a microbe had penetrated into a cell but had not the power of directly splitting off the fatty bodies; then these substances would not be immediately assimilable by it. Yet it would be able to obtain their possession, if it secreted a poison injurious to the cell, which would decompose the protoplasm. In such a case the fat would be liberated and could be assimilated by the micro-organism although the immediate affinity between the two may be a very low one. At any rate, these considerations might in so far be of interest as they touch upon an issue of biology and pathology, which has on the whole been somewhat pushed into the background of late years, since one has accustomed oneself in every infective process to think in the first place of a specific bactericidal action through the direct toxic substances of the body, its haptines, &c. This has led to our neglecting somewhat the simple possibility that certain micro-organisms may only be able to grow if certain conditions are given for their development and needs must perish if these conditions are not fulfilled. To my mind, this possibility can be important in many respects and is especially significant for our views on cancer immunity. At any rate, we are dealing in these questions with a highly complex field in which many possibilities are present, the most important being this difference of avidities.

It has been shown that the trypanosomes may alter their avidity for arsenic and thus acquire an apparent immunity. The contrary may occur in the case where the substance in question is not a poison but a nutritive body. Here we should be perfectly justified in supposing the avidity of the receptor to have become increased. The same thing may take place with micro-organisms which can physiologically diminish or increase their avidities. Thus in all these cases the struggle lies between the adaptability of the parasite and that of the host. The one whose adaptability in the last place is highest will remain victor. Of course this struggle is to a great extent influenced by indirect actions consisting in the secretion by each antagonist of dissolved substances hostile to the vitality and receptivity of the organism. On the part of the bacteria these substances are the toxins and the dissolved intracellular substances, on the part of the body the anti-substances.

A further rôle is played by actions of a protective and defensive nature. Thus we have shown that bacteria congregate in those parts where they find the most favourable conditions of nutrition, whilst the organism both by its the results have been good, but it has never seemed to me to be a perfect way of dealing with the condition. Theoretically it would be much better to detach the ureter completely, cutting the orifice obliquely, and attach it to a separate opening at the lower part of the pelvis. The difficulty in this case is the small size of the ureter and the consequent difficulty of manipulating it and attaching it so that there shall be no leakage at the point of junction with the pelvis. This difficulty is quite done away with by the method employed in the foregoing cases, and which the drawings reproduced will fully explain. By taking a piece of the pelvis along with the ureter we not only get something that we can handle easily but also an oval piece of tissue which can be much more accurately stitched to the new opening of the pelvis with much less danger of leakage. The details of the operation are as follows. An oval piece of the pelvis of the kidney containing the orifice of the ureter is excised, the greater extent of the oval being above the ureter. At the lower part the incision runs about a quarter of an inch below the point where the ureter leaves the pelvis, at the sides it is carried out to about half an inch, and at the upper part rather more. This piece being detached the orifice of the ureter is inspected and one blade of a pair of scissors is introduced into the ureter not quite down to the point where the ureter loses connexion with the pelvis, and the other blade being on the pelvic surface the scissors are closed and in this way a slit-like opening is made and the valvular orifice is got rid of. The wall of the ureter and that of the pelvis along this cut, and more especially at the lower angle, are now united by three or four fine catgut sutures. A piece of the lower part of the dilated pelvis is now cut away corresponding in size and shape to the above, and the ureter is then fastened into this opening by a series of Lembert catgut sutures. If deemed advisable a portion of the dilated pelvis may now be cut away and the opening stitched up in a linear direction. If possible it is well to avoid any connexion between this incision and that in which the ureter is attached as leakage is apt to occur at the angle of union. If such a connexion is made as was the case in the first patient I think it is well to put in a second row of Lembert's sutures at the junction with the oval so as to make it more secure. The kidney is now fixed high up in the usual manner. I think it is well to put a tube down to the kidney for a few days.

Harley-street, W.

AN IMPROVED PREPARATION FOR INTRAMUSCULAR INJECTIONS OF INSOLUBLE SALTS OF MERCURY IN THE TREATMENT OF SYPHILIS.

By F. J. LAMBKIN, L.R.C.P. & S. Irel.,
COLONEL, R.A.M.C.

Since Scarenzio in 1864 first suggested injections of insoluble salts of mercury in the treatment of syphilis certain obstacles have always existed in connexion with it which have undoubtedly militated against its being universally adopted as the best and by far the most convenient way of treating the disease—i.e., pain at the site of injection, painful nodosities, abscesses, and embolism. Although with the progress of knowledge and improved technique the first (as regards metallic mercury) has been reduced to a minimum, and the last three practically caused to disappear, still that they do exist even now, if to a limited extent, there can be no doubt, and this is the chief cause, and indeed in a great many cases the only one why some of the best known syphilologists of the day hesitate in recommending the intramuscular method before all others in the treatment of syphilis. Fournier, in his "Traité de la Syphilis," says: "Lastly, a weighty argument (which I have already developed in the previous remarks) which condemns the method is that by its inconvenience, and especially by the pain it inflicts on patients, it constitutes the best method for preventing patients continuing treatment." In the early days of treatment by this method the main causes of the difficulties alluded to were undoubtedly due, in the first instance, to the ignorance existing at this epoch as regards the necessity for employing antiseptic precautions in carrying out injections, and, secondly, to the unsuitability of the substances which had to be employed as vehicles for the suspension of mercury in the preparation used for injection purposes. The former has, of course, been long since remedied and pain (at any rate, where metallic mercury is concerned) has, as previously stated, been reduced to a minimum, but the other objection has existed more or less up to this day.

The substances which have been employed to hold the mercury in suspension are as follows: glycerine, gum water, olive oil, vaseline, oil of vaseline, and lanolin. Each of these has had its day, one being introduced from time to time as an improvement on the other, and in some respects they may have succeeded in this. Personally, I could never get away from one objection which was common to all—"being insoluble in the organism they entered the circulation as foreign bodies, and as such might possibly have produced nodosities, abscesses, and embolism." This, of course, is a most grave objection and has always been a source of anxiety to me; however, perhaps I ought not to grumble at the substances (lanolin and liquid paraffin) which I have been in the habit of using, as I have personally never seen any of these accidents follow their use; at the same time, there can be little doubt but that some of those grave accidents which have been recorded in connexion with intra-muscular injections of mercury must be put down to the use of these insoluble substances. Besides this main objection some of the above have others which are much against them. Glycerine and gum water are very irritating and painful, whilst olive oil, vaseline, and oil of vaseline are apt to go rancid. Some 18 months ago, in discussing this matter with M. Duret, a well-known French chemist, he suggested *palmitin* as a substitute for any of the above substances as a vehicle. Palmitin is a neutral fat derived from palm oil, having the same chemical composition as the palmitin of the human system. It is an ether glyceride of palmitic acid, it is therefore easily saponified in the fluids of the organism, being converted into a soluble alkaline palmitate and glycerine; thus it enters the circulation not as a foreign body like all substances hitherto used as vehicles. For close on 18 months I have been experimenting with palmitin as a vehicle and have practically adopted it as such at the military hospital, Rochester-row, and with the greatest success.

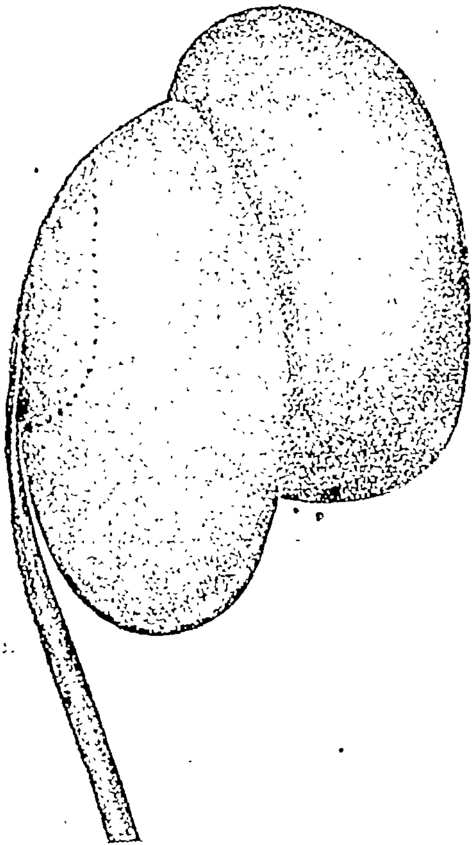
It is unnecessary for me to point out the preponderance of the advantages which I claim for palmitin over all other known substances as vehicles for the suspension of mercury in any form: (1) it is non-irritant and non-toxic; (2) is not so easily oxidised as the other components of human fat; (3)[1] being already a normal constituent of the human organism, easily saponified and soluble therein, it *does not* enter the circulation as a foreign body; (4) as a vehicle it makes a more homogeneous preparation for injection purposes than any other; and (5) its melting point can be raised and lowered with the greatest facility. I may here state that pure palmitin (which is the only preparation used) is a snowy white flocculent powder and great care is necessary to get it *pure*.

Analgesia.—The question of pain, although (so far as metallic mercury is concerned) this has been reduced to a minimum, still there is no doubt that it constitutes a grave objection in the practice of intramuscular injections, especially when calomel has to be employed. With a view, if possible, to abolish pain altogether after injections various substances have from time to time been introduced into the mercurial preparations used for that purpose—i.e., morphine, cocaine, beta-eucaine, &c.; these acting as they do almost at once will assuage any pain which may follow immediately after inoculation, but unfortunately this is not the kind of trouble we have, as a rule, to deal with, as the pain which bothers us is one which comes on two or three days after the injection, when the above local anæsthetics are fruitless. This is a very serious matter in any case, but especially as regards injections of calomel, for it is here that pain is most marked and severe; the consequence is that being hitherto unable to cope with it we have been forced more or less to abandon injections of calomel as anything like a routine method of treating syphilis and have only employed it under exceptional circumstances when pain was of no consideration. Hence was lost to us our keenest weapon for is formed below the attachment of the ureter. This goes on increasing till by-and-by the ureter comes to arise from the upper part of the dilated pelvis and thus the orifice tends to become blocked as the pouch fills with urine. But against this theory is the fact that the ureter in these cases does not come straight off from the dilated pelvis but is adherent to the wall of this sac for some little distance (from a quarter to half an inch), so that one may put one blade of a pair of scissors into the ureter and the other into the pelvis and cut the intervening wall of pelvis and ureter for a little distance without opening the cellular tissue beyond. This looks much more like a congenital malformation, as it is not easy to see how an organic connexion will form between the walls of the ureter and pelvis as the result of a simple distension of the latter.

---

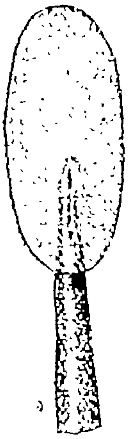
[1] Palmitin. In Stirling's work on "Physiology," p. 29, it is stated that neutral fats of adipose tissues of the body generally consist of a mixture of stearin, palmitin, and olein. Professor W. D. Halliburton in "Essentials of Chemical Physiology," p. 15, states that the fat cells are composed of three different fats called palmitin, stearin, and olein. Charles's "Physiology and Pathology," p. 84, says, "Palmitin is more abundant than stearin in human fats and is the chief component of most animal fats."

FIG. 1.



Showing line of incision in the pelvis of kidney and the attachment of the ureter.

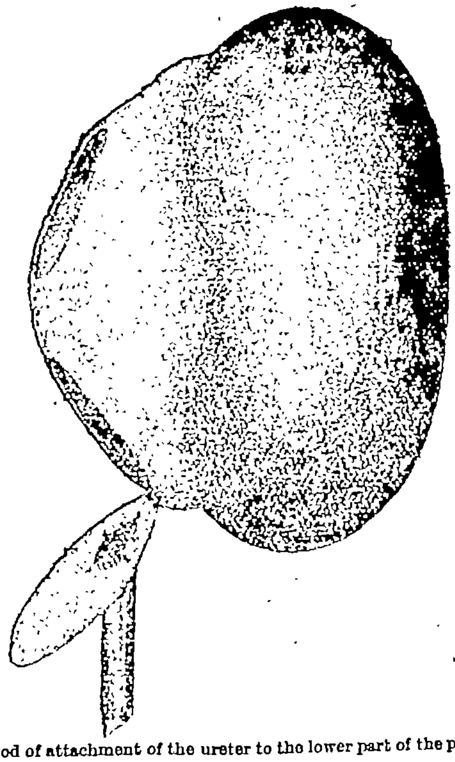
FIG. 2.



The upper end of the ureter and the adjacent portion of the pelvis of the kidney detached. The dotted line shows the incision for enlargement of the orifice.

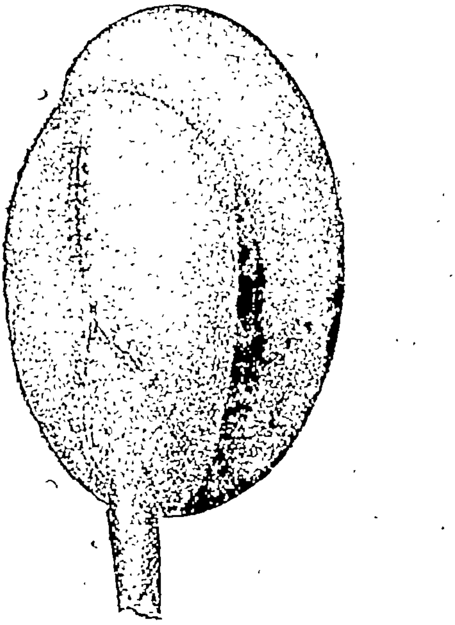
Treatment.—In previous cases of this kind I have contented myself with slitting down the valvular part of the orifice of the ureter from the interior of the pelvis, one blade of a pair of scissors being introduced into the ureter and the other remaining in the pelvis and the incision being carried as far down as the two structures are in intimate union.

FIG. 3.



Method of attachment of the ureter to the lower part of the pelvis.

FIG. 4.



Final result.

Fine catgut stitches are now inserted between the wall of the ureter and that of the pelvis, especially at the lower angle, so as to keep this new orifice patent.[1] In several cases

Hence was lost to us our keenest weapon for dealing with syphilis. It has always been my endeavour to overcome this drawback.

---

[1] Palmitin. In Stirling's work on "Physiology," p. 29, it is stated that neutral fats of adipose tissues of the body generally consist of a mixture of stearin, palmitin, and olein. Professor W. D. Halliburton in "Essentials of Chemical Physiology," p. 15, states that the fat cells are composed of three different fats called palmitin, stearin, and olein. Charles's "Physiology and Pathology," p. 54, says, "Palmitin is more abundant than stearin in human fats and is the chief component of most animal fats."

Being cognisant of the analgesic powers of creasote it struck me that *some combination between it and camphor* might possibly meet with success. With this in view I consulted Messrs. Oppenheimer and Co., who informed me that they manufactured *absolute creasote* from the ordinary product which is obtained from beechwood; that there is a very great difference between what is known as guaiacol and this purified creasote, the former constituting only about 20 per cent. of the bulk of beechwood creasote. The purified creasote is an intimate chemical substance consisting roughly of 20 per cent. of guaiacol, 40 per cent. of creasote, and 40 per cent. of monatomic phenyl; it is methyl-catechol and has the empirical formula of $C_6N_4O_{10}H_{18}$; it possesses double the bactericidal effects of pure carbolic acid when tested by the Rideal-Walker process. With this substance, in combination with camphoric acid, I have been experimenting for some little time now, and I may say at once that it has proved a thorough success as an analgesic in not only combating any pain which may immediately follow on an injection, but, *what is much more to the point, it apparently succeeds* admirably in preventing the occurrence of that after-pain *which comes on on the second or third day, especially after* calomel.

The abolition of pain after injections, I need not point out, is of the very greatest, if not of vital, importance to us syphilologists, not so much as regards metallic mercury (which never caused much), but in the case of calomel it is of prime interest. Syphilologists the world over have long considered calomel to be the most potent salt of mercury in its power over syphilis in all its stages, its action in this respect being truly remarkable; it is more active and energetic than any known salt of mercury, acting promptly when called upon in acute cases, whilst clearing up old-standing ones which may have resisted and baffled all other treatment. Nevertheless, in spite of all this, calomel has been limited to the treatment of certain cases and the idea of employing it in anything like a systematic manner has been more or less generally abandoned owing to one great drawback—i.e., the intense pain which was liable to follow its use as an injection, this latter usually coming on about the second or third day after inoculation and lasting with more or less severity for three or four days. As regards this pain, Fournier gives statistics collected by himself and Portalier of 473 cases of syphilis treated by injections of calomel; in 36 per cent. pain was slight, in 35 per cent. it was moderate, in 29 per cent. it was acute, and in 3 per cent. it was intolerable. This estimate coincides with my own experience and rather understates the actual amount of pain than otherwise. I have seen so many cases when this has been almost intolerable that as years went on I approached the giving of intramuscular injections by calomel with more or less dread and only employed them when absolutely obliged to from the nature of the case. Since I began to use this substance, absolute creasote and camphor, as an analgesic I have been giving intramuscular injections of calomel with impunity—in fact, during the last few months at the Military Hospital, Rochester-row, I have to a certain extent modified my method of treating syphilis, for, whereas previously patients undergoing injection treatment were put first on metallic mercury, latterly to begin with they are put on weekly injections of calomel; this rapidly causes the disappearance of signs and symptoms and then they are put on intramuscular injections of metallic mercury.

With reference to this latter it may be well to remark here a fact which has been long since noticed by myself as well as by others—i.e., that although the action of calomel on syphilis is so markedly energetic and rapid it is short-lived when compared with that of metallic mercury, hence the necessity of reverting to the latter at an early date. This combination between pure creasote and camphor possesses other advantages besides its analgesic powers—i.e., it is in the first place non-toxic (which cannot be entirely said of other suggested local anæsthetics) and is strongly antiseptic, being twice as much so as pure carbolic acid; besides which, being a viscous body, it lends valuable aid to the palmitin in making up a vehicle which will hold metallic mercury or calomel in suspension—in fact, the combination goes to form a most homogeneous preparation, much better in this respect than any I have ever seen before; its consistence at a melting point of 37° Centigrade (which is what I am at present using) could hardly be improved upon.

The following are the formulæ for the two mercurial creams:—

Hydrargyrum		10 grammes.
Equal parts of absolute creasote and camphoric acid	Creo-Camph	20 c.c.
Palmitin basis to		100 c c.

10 m. of above contains one grain of mercury.

Calomel		5 grammes.
Equal parts of absolute creasote and camphoric acid	Creo-Camph	20 c.c.
Palmitin basis to		100 c.c.

10 m. contains ½ grain of calomel.

Melting point 37° Centigrade.

Lieutenant-Colonel W. B. Leishman, R.A.M.C., has examined both of the above creams and found "both sterile and that bacteria would not grow in either."

Creo-Camph (otherwise camphorated creasote) is absolute creasote in combination with camphoric acid and is isolated as such from creasote obtained from beechwood by fractional distillation as methyl-catechol. As before stated, both these preparations form cream of almost perfect consistence and homogeneity. Both the metallic mercury and calomel are triturated with the other constituents by a special process which has been highly developed by Messrs. Oppenheimer. Both are very finely divided. Messrs. *Oppenheimer, to prevent any chance of over-dosing, supply* these creams in aseptules, each graduated to hold a *maximum dose of 15 minims.*

To sum up, I would briefly remark that, in my opinion, the substitution of palmitin, which is a *soluble constituent* of the organism, as a vehicle for the suspension of mercury in place of the insoluble substances hitherto in use, and the success which has followed the adoption of camphorated creasote as an analgesic begin a new era in the treatment of syphilis by intramuscular injections of insoluble salts of mercury; for, in the first instance, one great objection to the treatment—i.e., the introduction of insoluble foreign bodies into the circulation—is done away with, and in the second, pain has been practically abolished even in the case of calomel. It is needless for me to point out what abolition of pain means to most patients, be it ever so slight, but in this case it means much more from the surgeon's point of view, in that it places at his disposal the best and most energetic mode of dealing with syphilis without let or hindrance—i.e., injections of calomel.

SEPARATION OF THE ACETABULAR EPIPHYSIS OF THE FEMUR: ITS RELATION TO ADOLESCENT COXA VARA.

BY PERCY W. G. SARGENT, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE; FORMERLY SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA;

AND

HAROLD A. KISCH, M.B., B.S. LOND.,

LATE ASSISTANT IN THE X RAY DEPARTMENT; FORMERLY HOUSE SURGEON AND CASUALTY OFFICER, ST. THOMAS'S HOSPITAL.

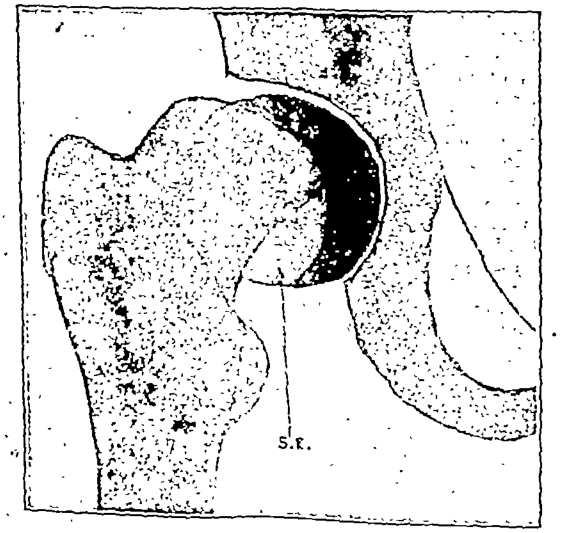
SEPARATION of the acetabular epiphysis of the femur, a condition formerly regarded as extremely rare, is now recognised as of not infrequent occurrence. The separation is usually diagnosed after some comparatively trivial injury to the hip-joint which leads to a skiagraph being taken. The importance of this separation in the etiology of adolescent coxa vara is also appreciated and the view has gradually been adopted that all cases of adolescent coxa vara have had a previous separation of the epiphysis. The following case, which was demonstrated at the clinical evening of the Medical Society of London on Feb. 11th last, is, so far as we have been able to ascertain, unique in that the boy presents a condition of recent separation of the right acetabular epiphysis without any knowledge that there is anything wrong whatsoever with the right hip-joint.

The patient is an epileptic, 19 years of age. On Dec. 23rd, 1906, he had a fit whilst in bed. He did not tumble out of bed but when he woke next morning the left hip was very painful and he was unable to walk properly. He managed, however, to hobble about. The leg continued to be painful, especially at night, and shortly afterwards he went to the National Hospital and was referred by Dr. F. E. Batten to one of us (P. W. G. S.), who sent him on to St. Thomas's Hospital for admission. This is the history he gave, but on careful inquiry we found that he had fallen out of bed in a fit about a year ago and that some time after he had some feeling that the left hip was not quite right and his friends told him that he limped. He has never had any sensation or pain in the right hip. He has had no illness of importance and shows no evidence of rickets or syphilis.

On examination it was found that the left leg was in a position of adduction, external rotation, and flexion, whilst the right leg was apparently normal. There was half an inch difference in the length of the two legs and the great trochanter was raised half an inch above Nélaton's line on the left side. No movement could be obtained at the hip-joint on the left side but on the right the movements were free, except for slight limitation of flexion and abduction.

A skiagram of the left hip (Fig. 1) shows that the acetabular epiphysis is separated and has rotated on two axes: (1) a horizontal antero-posterior axis; and (2) a vertical axis, so that the separated surface looks forward. The femur is displaced upwards and inwards so that the neck is situated in front of the separated surface of the epiphysis and projects above it. The skiagram of the right hip (Fig. 2) shows an extremely interesting condition. On this side the epiphysis is also separated but has only undergone rotation on the antero-posterior horizontal axis and has rotated upwards instead of downwards. *There is no rotation* on the vertical axis.

FIG. 1.

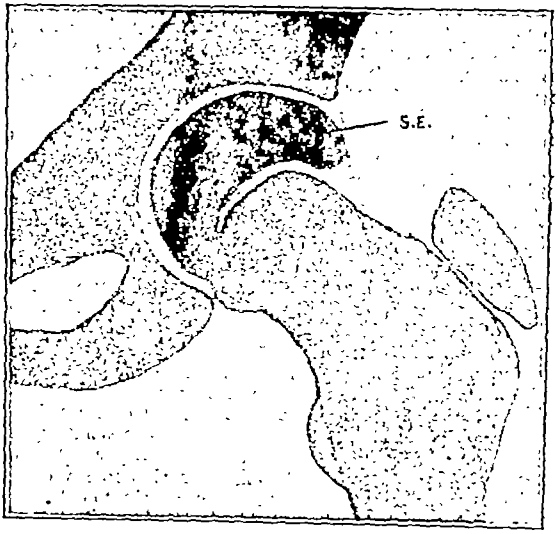


Reproduction of tracing of skiagraph of left hip.

The essential differences between the *two sides* are these: 1. On the left side the epiphysis has undergone a rotation on its vertical axis. 2. The epiphysis on the right side has rotated upwards on its antero-posterior axis instead of downwards as on the left side, and has undergone no vertical rotation. We believe that the clinical differences on the two sides depend entirely on this vertical rotation and are of opinion that the rotation occurred during the fit, muscular action pressing the neck of the femur against the epiphysis, thus causing rotation of the already separated epiphysis. The upward rotation on the right side is difficult to explain. We must assume that the separation on this side had not existed a sufficient length of time to allow the body weight to cause the downward movement, which apparently has occurred in all other cases. We can find no record or skiagram showing a similar position for the epiphysis.

During the last six years, 1901–06, ten cases with the diagnosis of "separated acetabular epiphysis" have been admitted to St. Thomas's Hospital. They were all males, the average age being 15·9 years, the extreme ages being 14 and 18 years. This patient's age is 19 years, rather older than the average age, but he is very undeveloped and skiagrams of his other epiphyses show that they correspond to those of boys about 14 or 15 years of age. From an examination of the skiagrams and notes of these cases and of 11 cases of coxa vara which present similar appearances we can differentiate two classes of this condition: 1. Where there is only rotation on an horizontal antero-posterior axis 2. Where there is rotation on both an horizontal and on a vertical axis. In the first class the symptoms are slight and there is only slight impairment of *mobility*. The treatment consists in wrenching under an anæsthetic and immobilising in the abducted position in a suitable *apparatus* for two or three months and then the use of patten and crutches for a year. The prognosis is excellent and we have seen skiagrams taken after this treatment has been carried out which show no evidence of abnormality whatever. In the second class the symptoms are more severe, and we may say that the greater the vertical rotation the *severer the* pain and immobility. This boy on his left side shows very great rotation and his pain has been very severe. The pain is due to pressure on the capsule. The treatment is more difficult. An attempt should be made under an anæsthetic *to wrench* the bones into place, but if not successful the neck *must* be screwed or nailed to the epiphysis, the femur first being rotated and abducted until the fractured *surfaces* are in apposition. The prognosis is worse than in the *first* class.

FIG. 2.



Reproduction of tracing of skiagraph of *right* hip.

If a case of separated epiphysis with a history of injury is untreated the deformity known as traumatic coxa vara results. Now the skiagrams of traumatic coxa vara are exactly similar to those of ordinary adolescent coxa vara, and as in the traumatic cases the injuries are always trivial, the view has, as we have already said, gradually developed that these conditions are really one and the same, that is, that all cases of adolescent coxa vara are due to a previous separation of the epiphysis. All will agree that this case would certainly *have* developed coxa vara on the right, apparently *sound*, *side*, and it is consequently the missing link of the chain *of* evidence connecting these two classes of coxa vara, *and* we may assume that other cases of coxa vara have *presented* this condition at some time previous to the *development* of their deformity.

The average age of 11 male cases of coxa vara admitted at St. Thomas's *Hospital from* 1901–06 was 16 years, 1½th months older than the *corresponding* cases of seperated epiphysis. There were *three female* cases and their average age was 13·5 years.

The clinical *history* of cases of coxa vara can be epitomised as follows: (1) *slight* limping and aching; (2) increased pain, *sometimes preceded* by slight trauma; and (3) deformity. These stages correspond to the pathological ones of (1) separation of epiphysis without vertical rotation; (2) rotation on vertical axis; and (3) coxa vara. Pain, more or less severe, commences as soon as rotation occurs. The severity of the pain depends on the rapidity and extent of the rotation. In the case we have just recorded the rotation was very rapid and extensive and the pain correspondingly great. If rotation is very gradual the pain may be very slight and in some cases absent altogether. This explains those cases of adolescent coxa vara where one finds well-marked deformity with no history of pain. The extent of the rotation on the vertical diameter is estimated by the extent of the curve of the lower margin of the faint shadow of the separated surface of the epiphysis as shown in the diagram (Fig. 1, S E.). The greater the rotation the nearer the arc of a circle this curve becomes, whilst in lesser degrees the curve is elliptical. The amount of antero-posterior curve, or rather deformity, in the neck of the femur depends on the amount of rotation of the separated epiphysis on its vertical axis.

The pathological change, which occurs at the epiphyseal line, is at present quite unknown. The skiagrams show no bony change. The disease apparently only occurs in the poorer classes, and does not appear to be due to any particular occupation. The reason why this condition is only demonstrable at the acetabular epiphysis of the femur is probably explained by the architecture of the joint. The weight of the body is transmitted through the pelvis, and the closely fitting bony cup of the acetabulum causes that pressure to act directly on the epiphysis. No other joint has this conformation and a corresponding pressure to bear.

In conclusion, we would urge the need of immediately skiagraphing all cases of slight limp or aching about the hip-joint in patients between about 12 and 18 years of age in order to detect the condition of separation in its earliest stage, and before the case passes into our second class.

Our best thanks are due to Dr. A. H. Greg of the x ray department of St. Thomas's Hospital for his assistance and for the use of his collection of skiagrams.

THE OPSONIC INDEX AND AGGLUTINATION IN CEREBRO-SPINAL MENINGITIS.

BY ALICE TAYLOR, L.R.C.P. IREL.

THE value of the opsonic index in the diagnosis and treatment of various forms of infections having been demonstrated by Sir A. E. Wright, it was thought probable that it might also prove of service in cases of cerebro-spinal meningitis. The opportunity for such investigation presented itself at the Children's Hospital, Great Ormond-street, London, for in the early months of this year eight cases of cerebro-spinal meningitis were admitted to the hospital. The following table gives shortly the important features of these cases:—

Table of Eight Cases of Cerebro-spinal meningitis.

Case.	Age.	Rash.	Lumbar puncture.	Organism isolated in culture.	Result.
1	13 weeks.	3 crops: (1) petechial; (2) erythematous; (3) elevated spots and face scars.	*	Gram-negative diplococcus.	Death.
2	7 months.	Purpuric.	Turbid.	Ditto.	"
3	3 months.	Vesicular.	No fluid obtained *	No growth.	"
4	4 years.	Erythema.	Cloudy fluid.	? Few intracellular cocci.	Recovery.
5	2 years, 5 months.	—	Cloudy fluid under pressure	No growth, very few intracellular diplococci.	"
6	2 years, 8 months.	—	Cloudy fluid.	Gram-negative diplococcus.	"
7	2 years, 5 months.	—	"	1 colony; no further growth.	—
8	1 year, 6 months.	Before admission.	Clear fluid.	Gram-negative diplococcus.	Convalescence.

* At the necropsy hydrocephalus, meningitis of vertex, little of base and sticky exudate on the posterior surface of the cord.

It will be seen that all these cases were proved, either by lumbar puncture or post mortem, to be cases of cerebro-spinal meningitis.

Method of investigation.—The method of investigating the opsonic index was that described by Sir A. E. Wright. The emulsion throughout was made from a culture on blood serum of meningococci isolated from the cerebro-spinal fluid of one or other of the patients. These meningococci were all Gram-negative. The emulsion was used alive. The stain was a strong solution of toluidin blue made up with sodium bicarbonate; this gave satisfactory results. The leucocytes were washed once in a solution of sodium citrate in sodium chloride and after that twice again in sodium chloride 0·9 per cent. The emulsion was also made up with 0·9 per cent. sodium chloride.[1] Considerable difficulty was, however, encountered in dealing with the organisms, for it was found that the older cultures underwent rapid degeneration during incubation. In the later cases in which a seven to ten hours' culture was used this degeneration did not occur and in these cases a very high index has been noted. Degeneration was shown by the swelling and irregular staining of the coccus and subsequently by its disintegration into a granular detritus.

The difficulty of working with an organism which so rapidly undergoes disintegration has also been noted by Davis in America and led to the (provisional) conclusion that the opsonic index was not delicate enough to be of any service in diagnosis or treatment.[2] In the earlier cases, where older cultures were used, the serum of the controls showed a high opsonic power; in the later cases, when a young culture was employed, the opsonic power shown by the controls was extremely small; whereas the serum from cases of meningitis showed enormously increased opsonic power, and the average number of organisms per leucocyte differed as much as 18 to 1·8, the incubation period being eight minutes in this case. The normal opsonic power appears unable to act until, according to Flexner,[3] autolytic enzymes are being set free. The thickness of the emulsion is also an important factor to regulate, for if the emulsion be too thick the number of organisms in the leucocytes with the patient's serum may become uncountable.

Whilst observing the opsonic index it was noted in the later cases that agglutination was a marked feature. This has been observed after an incubation of ten minutes in a dilution of 1 in 3. The controls throughout the whole series never showed any agglutination, nor was it present in slides without serum, where the emulsion was incubated with 1 part each of washed leucocytes and saline solution. It was also tested against tuberculous meningitis and typhoid fever; in neither case was agglutination present. In testing for agglutination alone a thick emulsion is to be preferred. The clumps are then very much larger and are spread along the edges of the smear in the same manner as the leucocytes, and the contrast between the control slide, thickly strewn with pairs and some tetrads of meningococci, and the patient's slide, almost or quite free from loose cocci but with clumps along the edges, is a striking feature.

As a result of these observations the following questions suggest themselves: 1. Is this high index pathognomonic of the disease? 2. Is it present in all forms of meningococcal meningitis? 3. Will it be possible, by the difference in the opsonic index or agglutination associated with it, to distinguish between the various forms of meningococci which have been shown by observers to give slight cultural and staining differences? Some attempt will be made to answer these questions in part, but a complete answer can only be obtained by further and more extensive investigations than it has been possible at present to carry out.

The following charts show the results obtained. Charts 6 and 7, and Chart 4 above Index 2, are marked $\frac{1}{10}$ of the scale of the early charts. In Chart 4 the opsonic index against the tubercle bacillus is also recorded with dotted lines. The presence of agglutination in the opsonic index slide is designated by +.

CASE 1.—The patient was a female, aged 13 weeks, who was taken ill seven days previously. The opsonic index was in the early stages low, becoming higher towards the end of the disease. In this case a vaccine was given which may have had some influence on the index.

---

[1] This strength of sodium chloride solution has been used throughout these experiments, for it was found on using emulsions made up with 0·9 per cent. sodium chloride and 1·5 per cent. sodium chloride concurrently, almost exactly the same opsonic index was obtained.

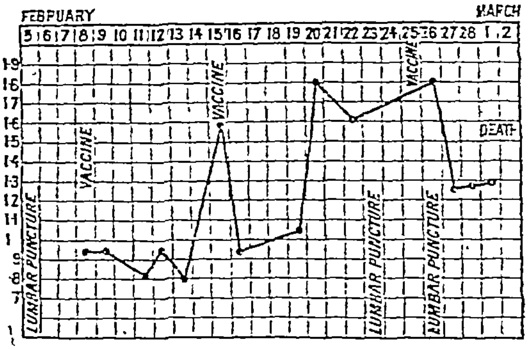
CHART 1.

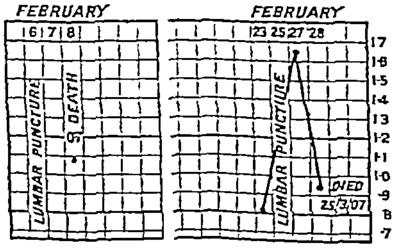


Case 1. Admitted on the seventh day of illness.

CASE 2.—The patient, a male, aged seven months, was taken ill five days previously and died on the eighth day of his illness. The index taken on the day of death was normal.

CASE 3.—The patient, a male, aged three months, was admitted in the third week of his illness. The opsonic index was only taken three times; on the second occasion it was high for the method then used. On examining a slide kept a tendency to form groups can be distinguished.

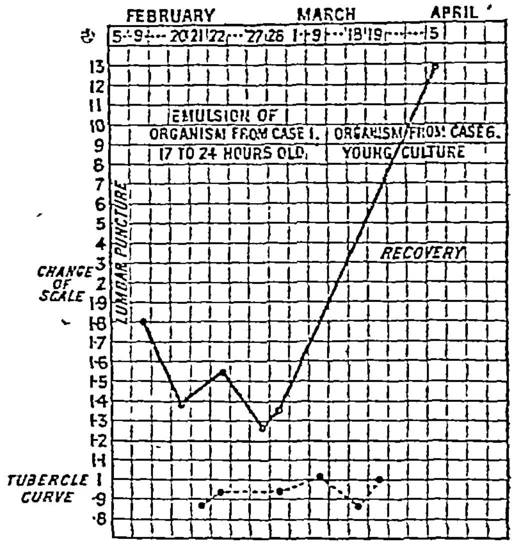
CHARTS 2 AND 3.



Cases 2 and 3. Admitted respectively on the fifth day and third week of illness.

CASE 4.—The patient, a female, aged four years, was admitted on the third day of her illness. The temperature remained continuously high for four weeks. The opsonic index to meningococcus was high on the eighth day of the illness. The opsonic index in this case having been taken by the two modifications used in these observations shows typically the difference in the index resulting from using a young culture. The index on this chart, after reaching 2, is marked $\frac{1}{10}$ of the size. It also shows the tubercle index remaining steady within normal variations.

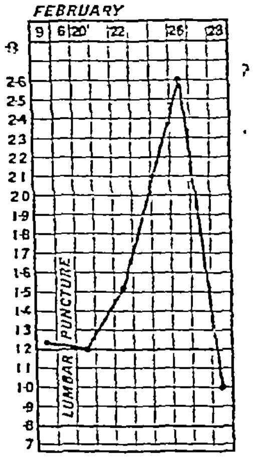
CHART 4.



Case 4. Admitted on the third day of illness.

CASE 5.—The patient, a female, aged two years and five months, was taken ill five days previously. The temperature remained high for six weeks. The opsonic index was at first 1·2 and towards the end of the illness rose considerably.

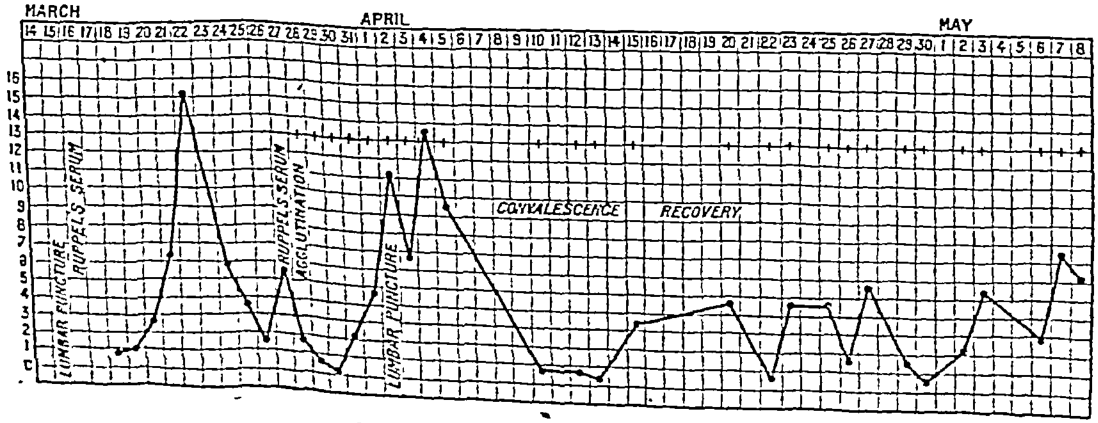
CHART 5.



Case 5. Admitted on the fifth day of illness.

CASE 6.—The patient was a female, aged two years and

CHART 6.



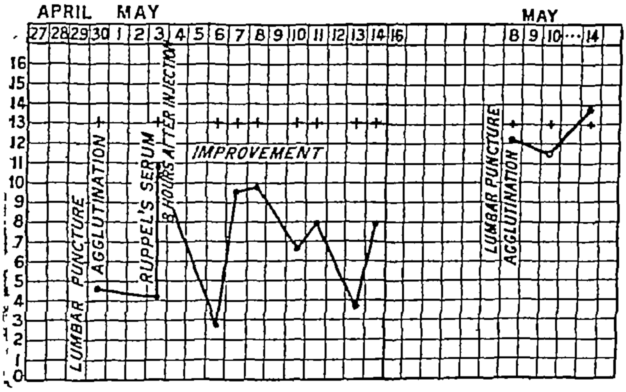
Case 6. Admitted on the fourteenth day of illness.

eight months. The opsonic index was at first low; it rose rapidly and remained high during the whole course of the disease, showing considerable fluctuations. Agglutination was noted first in this case on the twenty-eighth day of the illness and has since been continuously present. Convalescence set in in the sixth week of the illness. This patient was treated with two injections of Ruppel's serum. A considerable rise in the index followed each injection and agglutination was first noted after the second injection; there was at the same time also marked improvement in the general symptoms. On April 9th, the fortieth day of illness, the patient sat up and a week later appeared perfectly well. There was still, three weeks later, marked agglutination and the opsonic index fluctuated somewhat above the normal.

CASE 7.—The patient, a female, aged two years and five months, was admitted in the sixth week of illness. The rash appeared five weeks before and there was head retraction three weeks before; she was very wasted. The opsonic index, taken after admission, was above normal and a marked tendency to agglutination was present. This case had also received one injection of Ruppel's serum; eight hours afterwards the index was two and a half times higher, the temperature became normal, and the general symptoms markedly improved.

CASE 8.—The patient, a female, aged one year and five months, was admitted in the fifth week of her illness. There were rash and head retraction three weeks before. The opsonic index was 12·2 and agglutination was present.

CHARTS 7 AND 8.



Cases 7 and 8. Admitted on the sixth and fifth weeks of illness respectively.

In Cases 1 to 5 inclusive the opsonic index was taken with cultures from 17 to 24 hours' old, and an incubation period from 15 to 20 minutes was used. It was necessary to count the degenerate forms and granules within the leucocytes, a matter of some difficulty, and one which could not be considered altogether satisfactory. In Cases 6, 7, and 8 an emulsion[4] from a young culture from seven to 10 hours old was used. The resulting smears became as easy to count as those of other organisms. Chart 4 shows typically the difference obtained by working with a young culture, for whereas with old cultures an index of from 1·3 to 1·8 was obtained, with a young culture an index of 13 was obtained.

Agglutination associated with the opsonic index was first noted with Case 6, on the twenty-eighth day of the illness, and when the accompanying opsonic index was low. It has been similarly noted by Houston and Rankin in the Belfast epidemic.[5] It was observed first after the second injection of Ruppel's antitoxin serum obtained from a horse immunised by cultures of meningococci rendered pathogenic to mice and guinea-pigs by culture on special media. Agglutination was also observed on taking the opsonic index after admission to hospital in Case 7 in the sixth week of the illness and in Case 8 in the fifth week of the illness.

In the paper already referred to by Davis he states that on testing the agglutination (by the ordinary Widal method) normal serum never showed any agglutination even undiluted. Gordon[6] mentions two difficulties against employing agglutination diagnostically in cerebro-spinal meningitis by Widal's method: (*a*) the impossibility with the meningococcus to make emulsions absolutely free from all aggregations; and (*b*) the delay that occurs before agglutination takes place. By the method in conjunction with the opsonic index these difficulties appear to be overcome: (*a*) aggregations of cocci have sometimes been noticed in the preparatory smear to test the thickness of the emulsion but this has ceased to be heeded, since in every case after incubation in the liquid medium of serum and washed leucocytes the aggregations spontaneously disintegrate and no aggregations are ever found in the slides of the controls or the patients unless agglutination is present; and (*b*) in these observations ten minutes have been the time limit. The dilution of 1 in 3 might be suggested as too low; it has, however, already stood the test of many observations. Dilutions of 1 in 12 and 1 in 36 have so far given no result in ten minutes.

A suggestion has been made that the clumps might be formed in drawing out the smear: (1) they would not in that case be invariably present with an altered opsonic index; (2) they can be observed if one part each of agglutinating serum, an emulsion of the strain of meningococcus causing it, and of saline solution are incubated ten minutes, dropped on to a slide and allowed to dry without being drawn out; and (3) on testing the result of using an obviously over-thick emulsion it was found the micrococci tended to be drawn out in lines round the cells and the edges of the smear. From the limited observations that follow it would appear probable that this agglutination is specific to the strain of meningococcus eliciting it and gains corroboration by the accompanying opsonic index.

Next the agglutination reaction of the serum of Cases 6 and 7 was tested—first, against the organisms isolated from the cerebro-spinal fluid of Cases 2, 6, and 8, and in every case they respectively gave a high opsonic index and interagglutination. Secondly, against two strains of organisms derived from Belfast—Belfast B. from cerebro-spinal fluid; and Belfast M. from blood. In these two striking differences appear: 1. The serum of Cases 6 and 7 against either Belfast organism gives a normal index and no agglutination. 2 With serum of normal blood against Belfast B. a high opsonic power against a young culture is shown, and the average number of organisms per leucocyte in two of the observations, instead of being limited to three, were 18 and 44 respectively, whereas the serum of normal blood against young cultures of Belfast M. showed a very low opsonic power, as noted against the London organisms. And in this case this low opsonic power has not been excited to action by the serum of Cases 6 and 7.[7]

Conclusions.—From the above observations it is now possible in part to answer the questions set forth at the beginning of this paper.

1. Is a high opsonic index pathognomonic of the disease? It appears possible from these eight cases to obtain a definite opsonic index in cerebro-spinal meningitis, either working with an old or a young culture. A high index has been shown to be present in all the cases examined. This index may under certain conditions attain a very high altitude. In Case 4 it is seen that the tubercle index at the same time runs its usual course. Two or three cases of tuberculous meningitis tested during these observations gave within two or three days a tuberculous opsonic index above the normal and did not give a high index to this meningococcus. This high index appears to be due in these cases to the characteristic feature that normal serum has scarcely any opsonic power against a young culture of this organism. It is therefore probable that a high opsonic index is pathognomonic of the disease.

2. Is a high opsonic index diagnostic in all forms of meningococcal meningitis? The results obtained on testing the serum of the present series of cases against the Belfast organisms[8] show that a high index is not always obtained with different strains of growth and that a negative result may occur. So that although a high index indicates the presence of the disease a normal index does not negative its presence.

3. Will it be possible by the difference in the opsonic index or agglutination associated with it to distinguish

---

[7] Sera since received from Belfast from three cases of chronic cerebro-spinal meningitis severally give a high index and agglutination against *Belfast M.* Against *Belfast B.* and the organism from Case 6 these sera give no agglutination and a normal index.

[8] And the Belfast serum against the Belfast and London organisms.

between the various forms of meningococci which have been shown by observers to give slight cultural and staining differences? Among the organisms tested in these observations it appears possible to differentiate three strains or variations of organisms—Belfast B. from Belfast M. and the present London organisms by the high opsonic power against young cultures as constantly demonstrated with normal serum; Belfast M. from Belfast B. by its very low opsonic power against young cultures as constantly demonstrated with normal serum; and Belfast M. *from the present* strain of London organisms by the normal index and absence of agglutination with the serum of Cases 6 and 7, the same serum giving a high index and marked agglutination reaction against the London organisms. It appears probable in order to obtain the fullest effects from a vaccine or serum treatment that the strain of organism employed in its preparation is of great importance.

I am greatly indebted to Dr. A. E. Garrod, Dr. A. F. Voelcker, Dr. W. S. Colman, and Dr. F. E Batten for allowing me access to these cases and kindly permitting me to make use of their notes and treatment. Also to Dr. J. G. Forbes for supplying me with subcultures of the meningococci isolated by him in these cases. My thanks are also due to Dr. T. Houston for allowing me to publish results with organisms and serum from Belfast.

Queen-street, W.C.

AN INVESTIGATION OF SOME OF THE MORE UNUSUAL FORMS OF ACUTE CONJUNCTIVITIS.

BY A. C. HUDSON, M.D. CANTAB., F.R.C.S. ENG.,
HOUSE SURGEON AT THE ROYAL LONDON OPHTHALMIC HOSPITAL;

AND

P. N. PANTON, M.B., B.C. CANTAB., M.R.C.S. ENG.,
ASSISTANT DIRECTOR OF THE LOUIS JENNER CLINICAL LABORATORY, ST. THOMAS'S HOSPITAL.

THE bacteriological identification of the Koch-Weeks bacillus in 1885 and of the Morax-Axenfeld diplo-bacillus in 1896 as specific causes of conjunctivitis form important landmarks in the history of the study of this disease. The resulting types of inflammation are in most cases associated with such characteristic clinical features as to present a more or less diagnostic picture. In cases of doubt the diagnosis may be confirmed by an examination of films prepared from the discharge, the organisms having distinct morphological appearances and their cultural characteristics being rarely called for in making a diagnosis. Recently accounts of these organisms have been published by Inglis Pollock[1] and by Usher and Fraser,[2] whose papers dealing with the bacteriology of conjunctivitis are largely concerned with Koch-Weeks and diplo-bacillary infections and afford strong evidence that these organisms, together with the gonococcus, are responsible for the causation of the great majority of the more acute cases of the disease met with in this country. In any large clinic, however, a considerable percentage of cases of acute *conjunctivitis* is met with in which the clinical features would appear to present no such generally recognised relation to their etiology. The aim of the present inquiry has been the investigation of cases of this nature met with by us during a *period* of 15 months, including several cases of gonorrhœal conjunctivitis, while cases of Koch-Weeks and diplo-bacillus conjunctivitis have been entirely, or almost entirely, omitted from this account, the cases encountered having been diagnosed either from clinical features or from film preparations, and no special media for the demonstration of these organisms having been employed.

TECHNIQUE.

In every instance two or more film preparations were made from the discharge and a culture was taken on to some form of solid medium, in most instances blood serum. One of the film preparations was stained by Gram's method and a second film was treated by Leishman's stain, whenever a cytological examination of the exudate was considered necessary. With the exception of some cases of gonorrhœal *infection*, in which an attempt at cultivation failed, no diagnosis was made from film preparations alone. In all, 105 cases were thus examined, but a certain small proportion of these include cases in which either the Koch-Weeks or Morax-Axenfeld bacillus was, in all probability, the main factor at work and are considered here only to complete the account of the other organisms present in addition. In a few cases films and cultures were taken also from other lesions in the body when these were thought to have any bearing upon the condition of the eyes. The cases were derived mainly from the Royal London Ophthalmic Hospital; a considerably smaller number from the ophthalmic department of St. Thomas's Hospital are also included. The organisms met with were in order of frequency a diphtheroid bacillus (60 times), a white staphylococcus (28 times), the *gonococcus* (27 times), the staphylococcus aureus (24 times), a streptococcus (10 times), an intermediate staphylococcus (3 times), the diphtheria bacillus (twice), and an unclassified coccus (once).

The cases are grouped under the heading of the various organisms present, but since a mixed infection was frequent some overlapping is unavoidable.

GROUP 1.—STREPTOCOCCI.

There were altogether ten cases of streptococcal infection, and in each case an attempt was made to procure the full cultural characteristics of the organism; in two instances, however, owing to the additional presence of a diphtheroid bacillus the streptococcus could not be isolated. In *one other* case the diphtheria bacillus, and in another both albus and aureus were present in addition; the former case is considered under Group 7. In the two cases in which the streptococcus was not isolated one was a severe attack with membrane formation, the other of moderate severity only and unaccompanied by actual membrane. Five of the streptococci isolated were classed on the evidence of Gordon's tests as the streptococcus pyogenes according to the classification of Andrewes and Horder.[3] In one of these five cases, a child, aged one week, a similar organism was *present also* in a sloughing hæmatoma of the face, and the fact that the mother died three days after delivery, presumably from some septic condition, points to the maternal passage as the probable source of infection. One of the pyogenes cases was accompanied by the diphtheria bacillus; there was well-marked membrane formation in this case and corneal infiltration. In the remaining three cases membrane formation was present in each instance and in two cases the eye was destroyed. A different variety of streptococcus was isolated in two instances and should probably be classed with the streptococcus fæcalis group. The cultural characters were almost identical in the two cases. The coccus was Gram-positive and occurred in chains of from 10 to 20. On agar slant typical streptococcal colonies were found. On jelly slant, at 22° C., no liquefaction. Litmus milk: acid, no clot. Gordon's media affected were: maltose, salicin, lactose, xylose, raffinose, arabinose, mannite, dextrose, and glycerine. Unaffected: erythrite, sorbit, and cane sugar. These media were identical in the two cases with the exception that litmus glycerine was acidified by the one organism and not by the other. In neutral red broth, anaerobically, a green fluorescence was produced by one organism only.

The occurrence of this same organism, of unusual characters, is of the more interest since the patients were brothers who attended the hospital at about the same time, and there is little doubt that they infected each other. Of these brothers one lost his eye; the other had only a mild attack of conjunctivitis which was associated with the onset of measles and which cleared up rapidly, affording a good example *of the difference* of personal resistance to the same organism. In another case, occurring in a small child with severe conjunctivitis accompanied by membrane formation, a streptococcus of unusual cultural characteristics was obtained. The organism was Gram-positive and occurred in very long chains. It formed very delicate colonies on agar and grew on jelly without liquefying it. It was transferred into a large number of Gordon's media and, with the exception of sorbit, acidified all of them. It produced green fluorescence in neutral red broth anaerobically. The organism was inoculated into the peritoneal cavity of a mouse and caused death in 12 hours; the streptococcus was recovered from the spleen, blood, and peritoneum.

[3] F. W. Andrewes and J. T. Horder: THE LANCET, Sept. 15th, 1906, p. 708.

The nine cases in which streptococci were considered the causative factor include some of the most severe cases met with in the series. In one case, however, in which the conjunctival inflammation preceded the onset of measles the symptoms were of a very mild character. The main clinical features are tabulated below:—

Unilateral	3	Ulceration of lid margins	2
Bilateral	6	Impetigo	2
Severe	5	Nasal discharge	1
Moderate	3	Ear discharge	1
Mild	1	Lymphatic glands enlarged	2
Discharge { Thin	7	Antecedent measles	3
Discharge { Purulent	2	Highest temperature recorded 101° F.	
Membrane on conjunctiva	5		
Pellicle[4] on conjunctiva	1		

The following are clinical notes of illustrative cases:—

CASE 1.—A female, aged one year and two months. O.P., R.L.O.H., April 8th, 1907 (Mr. J. H. Parsons). Left eye inflamed four days, left lids red, but not much swollen. Palpebral and bulbar conjunctiva injected and slightly swollen. Very superficial membrane on palpebral conjunctiva of both lids, which could not be stripped off without some hæmorrhage. Thin muco-purulent discharge. Cornea normal. Left pre-auricular gland palpable. Right eye normal. Chronic discharge from left ear. At the last attendance, five days later, the condition had considerably improved.

CASE 2.—A male, aged one year and three months. I.P., R.L.O.H., Jan. 1st, 1907 (Mr. J. H. Fisher). Right eye affected three days. Right lids œdematous, not brawny. Thick yellowish white membrane on conjunctival surface of both lids, which could not be removed without much bleeding. Some muco-purulent discharge. Right cornea very hazy. Left eye normal except for small patch of membrane on conjunctiva of left lower lid. No enlargement of lymphatic glands. Red spot on right cheek and forefinger. General condition fairly good. The disease rapidly progressed to a disastrous issue. Four days after admission the entire right cornea had become infiltrated and staphylomatous, the membrane on the conjunctiva at this time stripping fairly easily and leaving bleeding spots. Left eye normal. Right eye subsequently excised. Child left hospital one month after admission. Right socket was then clean except for small slough at the bottom, and urine contained no albumin.

CASE 3.—A male, aged two years and three months. I.P., R.L.O.H., Jan. 10th, 1906 (Mr. J. B. Lawford). Whooping-cough eight months ago; delicate ever since. Bronchitis 14 days ago. Right lids swollen considerably. Palpebral and bulbar conjunctiva much swollen. Muco-purulent discharge. Purulent mucocele. Deep haze of right cornea. Left eye normal. No enlargement of lymphatic glands. Affection of right cornea progressed rapidly, so that three weeks after admission the entire central portion had become yellow and staphylomatous. A fortnight later the eye was excised, the conjunctival inflammation having then almost subsided and there being no regurgitation from the lacrimal sac. Convalescence uneventful.

CASE 4.—A male, aged four years. O.P., R.L.O.H., Feb. 2nd, 1906 (Mr. Fisher). Brother of preceding patient. Very slight swelling of lids of both eyes with general conjunctival injection and a little watery discharge. Three days later it was reported that the patient had developed measles, but that the eyes were much better.

GROUP 2.—STAPHYLOCOCCUS AUREUS.

This organism was present in 24 cases, in 19 of which it was either the only organism present or was associated with either a white staphylococcus or a diphtheroid bacillus; in these cases it is classed as the causative organism of the disease. In the remaining five cases it was associated with the gonococcus twice, with the Klebs-Löffler bacillus, the Koch-Weeks bacillus, and a streptococcus, once each; in these cases it is considered as a secondary, though not necessarily a negligible, infection.

In view of the fact that the various staphylococci and other pathogenic organisms have on occasion been obtained from the normal conjunctiva, and that many of the attempts to produce by them experimental conjunctivitis in man and animals have failed, the majority of investigators into the bacteriology of conjunctivitis appear to regard the possibility of these organisms causing the disease with considerable reserve. Inglis Pollock[5] says, in agreement with Morax and Petit: "The pneumococcus and the Klebs-Löffler bacillus have occasionally, while the streptococcus and staphylococcus have as a rule, been found on the normal conjunctiva. Consequently the mere finding of these four organisms does not suffice for the diagnosis that a given case is due to them. ...... It is necessary to take into account the number of the microbes, their arrangements ...... etc." Similar views with regard to staphylococcal infection are expressed by Axenfeld[6] and other writers[7]; yet the various staphylococci and even streptococci are found in the normal skin, and no one doubts that they may on occasion give rise to a subcutaneous abscess; nor can a frequent failure to produce conjunctivitis be accepted as convincing, and, indeed, successful results have been recorded. In these cases no attempt has been made to estimate the number of microbes present, but their arrangement in the films was in each case noted. If the nature of the cells in the discharge plainly indicated an acute inflammation, if a culture taken from the fluid yielded an organism of known pathogenicity, and if similar organisms were present in the films (and preferably within the cells), that organism was considered the causative agent.

In 19 of the cases in this group, therefore, the causative agent was considered to be the staphylococcus aureus In three of these cases cultures were also taken from other lesions present in the body. In one case a pure culture of the staphylococcus aureus was obtained from the pus on incising an abscess of the neck; in this case, a small child, the conjunctival condition had progressed to complete loss of the eyes and the child subsequently died from septic absorption. In one case a nasal discharge was present and from this a white staphylococcus and the micrococcus catarrhalis were obtained, but no aureus. In the third case an impetiginous condition of the scalp was present and aureus was obtained from one of the lesions; it is possible that the conjunctiva was secondarily infected from the head.

In the great majority of all the cases films from the discharge showed numerous microphages, many of which were greatly degenerated, the organisms appearing for the most part as Gram-positive diplococci, a certain number of these being within the phagocytes. It was exceptional to see a staphylococcal arrangement in the films and, if no cultural tests are made, both these and other organisms are liable to be mistaken for the pneumococcus. In every instance large, bright yellow colonies of a Gram-positive staphylococcus were obtained upon agar and in nearly all cases these were subcultured on to gelatin and produced liquefaction in from 24 to 48 hours. This early liquefaction of gelatin is considered by Axenfeld[8] and others to be a good test of the relative pathogenicity of the various staphylococci.

In a few cases cultures were taken from the eye on two separate occasions, in each instance with identical results. As a control three strains, chosen indiscriminately, were passed through all the ordinary media and in addition through all Gordon's carbohydrate tests. The results were found to differ in no way from those obtained with various strains of aureus derived from other parts of the body in disease. One of these strains was injected into the vein of a rabbit; the animal died in ten hours; no lesions were found post mortem and a pure culture of a *white* staphylococcus was obtained from its spleen. A further inoculation of the original culture was made into the hind leg of a guinea-pig and resulted in a local abscess; the animal was killed one week later and cultures were taken from the spleen and the abscess; in both cases a *white* staphylococcus only was obtained. This coccus on being submitted to Gordon's tests gave results absolutely identical with those of the original yellow coccus. The result is of interest as indicating the possibility of an aureus losing its power of pigment production and appearing as an albus, though still retaining its other cultural characteristics.

The 19 cases in which the staphylococcus aureus was believed to be the causative organism were on the whole of severe type; only four could be designated as mild. The leading features of the 18 cases of which clinical notes are available are presented in the following table:—

Unilateral	7	Ulceration of lid margins	3
Bilateral	11	*Impetigo*	5
Severe	8	Nasal discharge	2
Moderate	6	Ear discharge	2
Mild	4	Lymphatic glands enlarged	8
Discharge { Thin	16	Lymphangitis of face	1
Discharge { Purulent	2	Antecedent measles	3
Membrane on conjunctiva	5	Highest temperature noted 100° F.	
Pellicle on conjunctiva	1		

The following are brief notes of illustrative cases:—

CASE 5.—A female, aged 27 years. O.P., R.L.O.H., Oct. 8th, 1906 (Mr. A. Lawson). Both eyes inflamed 24 hours. Slight injection and very slight swelling of conjunctiva of both eyes. A very little watery discharge. Cornea normal. Both preauricular glands just palpable but not tender. Four days later the patient was quite well, except for slight stickiness of lids after sleep.

---

[4] By the term "pellicle," used in this and subsequent tables, it is intended to describe a coherent sheet of fibrinous material which could be stripped off, leaving an injected but not bleeding conjunctival surface, in contradistinction to true membrane which could not be separated without hæmorrhage.

[8] Loc. cit.

CASE 6.—A male, aged 15 years. I.P., R.L.O.H., April 3rd, 1906 (Mr. W. T. H. Spicer). Right eye watery and painful three days; running from nose and sore throat for same period. Right lids very slightly swollen with congestive discolouration. Conjunctiva of both lids covered by a yellowish-grey pellicle which could be fairly easily detached, leaving an injected, but not swollen, conjunctival surface. Bulbar conjunctiva considerably injected but not swollen; pellicle did not extend to it. Watery discharge. Cornea not affected. Infection of skin of both lid margins with linear distribution on upper, in circular patches on lower, lid; large angular area at outer canthus. Infective process had proceeded to varying extent in different areas, so that it could be seen to be initiated by a subcuticular infiltration covered by a shiny cuticle which later lost its lustre, giving rise eventually to an opaque, greyish membrane. Right preauricular gland enlarged, hard, and tender; cervical glands on both sides of neck palpable. Red, slightly papular, eruption on right side of face. Left conjunctiva and lids normal. No membrane on fauces. Two days later left conjunctiva became slightly injected and eye watery. A week later, when the patient was discharged from hospital, there remained only slight swelling of right lids.

CASE 7.—A female, aged seven years. I.P., S.T.H., July 20th, 1906 (Mr. Lawford). Left eye affected five days. History of exposure to diphtheritic infection. Child pale and fretful. Left eye: lids swollen, closed, and somewhat brawny. Palpebral conjunctiva covered by a thin, yellowish pellicle which extended to both fornices and slightly on to the bulbar conjunctiva, and on separation left a bleeding surface; slight chemosis and congestion of bulbar conjunctiva. Muco-purulent discharge. Cornea bright. Left preauricular gland enlarged. Right eye normal. 6000 units of diphtheritic antitoxin were given shortly after admission to hospital. Highest temperature during stay in hospital 100° F. Patient was discharged in 11 days, when the swelling and membrane had nearly disappeared.

CASE 8.—A female, aged seven years. I.P., R.L.O.H., Sept. 29th, 1906 (Mr. R. M. Gunn). Yellow sty on left lower lid noticed four days ago. Left eye closed, cheek swollen, and preauricular gland enlarged two days. Discharge from nose noticed 24 hours. Left eye: greyish yellow absolutely adherent membrane involved almost entire margin of upper and outer half of margin of lower lid: great induration of lids; palpebral conjunctiva not seen, bulbar conjunctiva hyperæmic. Some thin discharge. Right eye: similar membrane on outer part of upper lid margin; did not extend on to conjunctiva, which was normal. Cornea normal. Lymphangitis of left side of face and tender swelling of right and left preauricular and cervical glands. Membrane inside left nostril. Fauces normal. Knee-jerks present. Three days later small circular patch of membrane in skin of face just below right lower lid. A week after admission the condition had greatly improved, but there was a little thin greyish membrane in the conjunctiva of the left lower lid continuous with that on the cutaneous surface; conjunctiva elsewhere simply thickened and injected; bead of yellow discharge at inner canthus. A week later patient was discharged cured.

In the following case the Koch-Weeks bacillus was found associated with staphylococcus aureus.

CASE 9.—A female, aged 21 years. O.P., R.L.O.H., Feb. 14th, 1906 (Mr. E. Treacher Collins). Left eye excised three years ago. Sore throat and swelling of glands in left side of neck four days. Swelling of lids and discharge from left conjunctiva three days. The conjunctiva of the left socket presented a shaggy yellow appearance owing to a superficial necrosis of the conjunctiva of the lids; a similar process had involved the lid margins around the bases of many of the lashes. Much flaky yellow discharge. Some œdema of left side of face; left preauricular and cervical lymphatic glands considerably enlarged and slightly tender. Right eye normal; slight œdema of right side of face. Hyperæmia of fauces; no membrane. Temperature 99·8° F. Patient looked and felt fairly well. Four days later the conjunctiva of the socket was almost normal in appearance.

In this case the clinical features were so much at variance with those characteristic of a simple Koch-Weeks infection as strongly to suggest that it was the staphylococcus aureus which had played the chief rôle in the production of the clinical picture.

GROUP 3.—AN INTERMEDIATE STAPHYLOCOCCUS.

This organism was present three times, twice in pure culture and once in association with a diphtheroid bacillus; in each case it was considered the cause of the lesion. In each instance cultures of a Gram-positive staphylococcus were obtained, which, after prolonged exposure to sunlight, remained of a colour intermediate between aureus and albus. In one case a subculture upon gelatin showed commencing liquefaction in 48 hours, becoming complete in six days. In the remaining two cases the fullest cultural characters were taken and were found to be similar to those obtained from the aureus strains of the preceding group. The three cases occurred in children under six years of age. The first case was a rather acute, and extremely intractable, bilateral conjunctivitis. There was a watery discharge with a few flakes, slight thickening of the lid margins, and some enlargement of both preauricular lymphatic glands. The second case was unilateral and associated with vesicle formation on the lid margins, followed by superficial necrosis which extended to the palpebral conjunctiva. The preauricular gland was enlarged and the temperature reached 101° F. The third case was a mild bilateral conjunctivitis with superficial membrane formation in both lower fornices.

GROUP 4.—AN UNCLASSIFIED COCCUS.

This was present in one instance and was associated with a diphtheroid bacillus. The films showed numerous microphages and a number of Gram-positive diplococci, some of which were intracellular. On agar small, round, white colonies were obtained which were intermediate in size between those usual for a streptococcus and those for a staphylococcus; they consisted of Gram-positive cocci in pairs and small clumps; in broth they appeared in small clumps and in short chains of two and four. In neutral red broth they grew well anaerobically but without changing the colour of the medium. Gelatin was liquefied in eight days. Milk and lead acetate were unaltered. No indol was formed in peptone broth. Of the carbohydrate media, lactose, maltose, cane sugar, and arabinose were acidified; xylose, mannite, salicin, raffinose, erythrite, and sorbit were unaltered. The coccus was non-pathogenic to a guinea-pig. We have isolated an exactly identical organism from a case of acute cellulitis. The organism appears to have some characters common to both the *streptococci* and *staphylococci*. The case from which it was derived in this instance was a unilateral conjunctivitis without corneal lesion in a child five years of age. There was considerable swelling of the conjunctiva with thin mucinoid discharge containing a few thicker flakes. The preauricular lymphatic gland on the same side as the affected eye was just palpable. The patient did not attend the hospital a second time.

GROUP 5.—STAPHYLOCOCCUS ALBUS.

This organism occurred altogether 28 times. On 12 occasions it was associated with other pathogenic organisms—namely, aureus five times, gonococcus three times, Koch-Weeks bacillus twice, Morax-Axenfeld bacillus, and a streptococcus once. In the remaining 16 cases it was either the only organism present or was associated with a diphtheroid bacillus. These 16 cases were accompanied by a considerable conjunctival discharge, the cells in which were mainly polynuclear; in the great majority of the films Gram-positive cocci were present, and many of these were inside the leucocytes. Large white colonies were obtained on agar in each case and these remained white on being exposed to the light for some days. In the majority of cases a subculture was taken on to gelatin and this was, as a rule, liquefied in from two to (more commonly) seven days. In three cases cultures were taken also from a nasal discharge which was present; on one occasion albus only was grown from the nose, once albus and the micrococcus catarrhalis, and once albus and aureus. In the last case the complete cultural characters of the albus, from the eye and from the nose, were investigated. The results were strictly identical in two cases.

Since a white staphylococcus is stated to have been frequently isolated from the normal eye, and since this class of organism is frequently one of low virulence, the question has arisen as to whether it can ever give rise to an acute conjunctival infection. In 16 out of these 28 cases this was the only organism of known pathogenicity found; it was present not only in the cultures but as a rule in the films and frequently within the phagocytes; moreover, in three cases it was present also in another, and possibly the primary, lesion. If albus is not allowed to be the cause of the infection it must be supposed either that a known causative agent was overlooked, or that some unknown organism was the cause of the disease. Every precaution was taken to guard against the former contingency and the latter supposition seems unnecessary, for some species of albus approach closely to the virulent staphylococcus aureus in their cultural characters, and there is a wide range both in the virulence of any particular organism and the resistance of any particular person; there is, too, sufficient evidence, both clinical and experimental, that a white staphylococcus can produce an acute inflammation. The cases in which a staphylococcus albus appeared to be the causative organism were almost all of mild type. In one case, however, a wasted unhealthy child, the infection was of a very severe character.

The main clinical features are presented in the following table:—

Unilateral	5	Ulceration of, or membrane on, lid margins	2
Bilateral	11	Impetigo	6
Severe	1	Nasal discharge	4
Moderate	1	Lymphatic glands enlarged	5
Mild	14	Lymphangitis of face	1
Discharge { Thin	15	Antecedent measles	3
Discharge { Purulent	1	Highest recorded temperature 99·4° F.	
Membrane on conjunctiva	2		
Pellicle " "	2		

The following are notes of illustrative cases:—

CASE 10.—A female, aged 19 days. O.P., R.L.O.H., April 6th, 1906 (Mr. P. Flemming). Discharge from eyes noticed third day after birth. Some swelling of lids of both eyes. Palpebral conjunctiva succulent and purplish. Muco-purulent discharge. Corneæ normal. Eyes quite well in five days.

CASE 11.—A female, aged 30 years. O.P., R.L.O.H., Sept. 24th, 1906 (Mr. W. Lang). Right eye affected 36 hours. Pink œdema of both right lids, extending inwards to nose and outwards on to cheek. Palpebral and bulbar conjunctiva considerably swollen; slight follicular enlargement. Thin discharge. Cornea normal. Right preauricular and cervical lymphatic glands enlarged. Left eye not affected. Temperature 99·4° F. Condition of eye improved rapidly but three days after the first attendance the left conjunctiva became injected and slightly swollen without enlargement of lymphatic glands. Both eyes were almost well four days later.

CASE 12.—A male, aged 13 years, O.P., R.L.O.H., Oct. 24th, 1906 (Mr. Lawford). Impetigo of left foot "on and off for a long time." Right nostril sore for three or four months. Right eye affected four days. Right lids swollen and indurated; many small flattened vesicles on margins of both lids. Palpebral conjunctiva very red, swollen, and follicular. Discharge thin with a few flakes. Cornea normal. Right preauricular and submaxillary lymphatic glands much swollen. Impetiginous sores on toes of left foot; glands in left groin enlarged. Temperature 99° F. Rapid improvement under treatment.

CASE 13.—A female, aged one year, O.P., R.L.O.H., Feb. 14th, 1906 (Mr. Gunn). Discharge from right eye five days. Ulceration of lower lid noticed one day. Slight swelling of right lids; some ulceration of skin at inner canthus. Palpebral and bulbar conjunctiva slightly swollen; superficial yellowish grey necrosis of conjunctiva of both lids. A very little thin discharge. Cornea normal. Left eye not affected. A week later the condition of the conjunctiva had greatly improved, but a minute corneal ulcer had developed. This had healed 17 days later.

The line of treatment adopted in the staphylococcal and streptococcal infections was as follows. In those cases in which the conjunctival inflammation was not associated with membrane formation or ulceration of the lids the conjunctiva was brushed over daily with a solution of silver nitrate, usually of the strength of five grains to the ounce and the conjunctival sac was washed out every four to six hours with some antiseptic lotion: perchloride of mercury in the strength of one part in 10,000 appeared to be the most satisfactory for this purpose. Where membrane formation was present a 20 per cent. solution of argyrol was used instead of nitrate of silver, and was found to have no tendency to produce extension of the necrotic process, such as has been observed in cases of this type after the use of silver nitrate. In those cases in which there was an associated infection of the skin of the lids or their margins without corneal lesions the application of boric fomentations to the lids, by bringing about a rapid restoration of the skin to a healthy condition, was found to act as a valuable adjuvant to the treatment of the conjunctival sac. Corneal ulceration appeared to afford a contraindication to the use of fomentations. The frequent application of moist heat to the lids in the form of hot bathing was found to have a beneficial effect in cases with this complication. In the more severe cases the general condition of the patient was frequently a factor demanding special attention. In a few cases a tardy convalescence was associated with a residual infection of the lash follicles, evidenced by thickening of the lid margins and hypersensitiveness when the cilia were stroked with the finger; satisfactory progress was usually maintained by daily epilation of loose lashes and scrubbing of the lid margins with a pledget of wool soaked in a 15 per cent. solution of protargol.

A percentage comparison of the main features met with in the cases associated with the streptococci, staphylococcus aureus, and staphylococcus albus gives the following results:—

—	Unilateral.	Bilateral.	Severe.	Mild.	Membrane.	Follicle	Cornea involved.	Enlargement of lymphatic glands.	Impetigo or ear discharge.	Nasal discharge.	Antecedent measles.
	%	%	%	%	%	%	%	%	%	%	%
Streptococci ...	33·3	66·7	55·5	9·0	55·5	11·0	33·3	22·2	33·3	11·0	33·3
Staphylococcus aureus	37·7	62·3	44·4	22·2	27·7	22·2	33·3	44·4	37·7	11·0	15·8
Staphylococcus albus	31·0	69·0	6·25	87·5	12·5	12·5	18·7	31·25	37·5	25·0	18·7

The great majority of these infections occurred in young children. In all the groups a thick purulent discharge was rarely met with, the character of the discharge being usually glairy with some solid flakes, or watery. Conjunctival hæmorrhages, so frequently met with in Koch-Weeks conjunctivitis, were observed in only two of the cases, both albus infections; an associated "angular" affection of the lid margins was not met with. A possible exposure to contagion was noted in one of the aureus and in one of the albus cases, and in the mild streptococcal affection occurring during the prodromal stage of measles.

From the above considerations it is evident that the clinical symptoms in the various infections presented many points of similarity, but that the severity of the type of infection showed a direct relation to the generally recognised pathogenicity of the causative type of organism. Membrane formation was met with in association with all the organisms in the group. The phenomenon of membranous formations was particularly observed, and was met with in various forms. In some of these a mere fibrinous pellicle was present adhering loosely to a conjunctival surface which presented when exposed an injected or granular appearance. In other cases the inflammatory process had apparently proceeded further, resulting in the destruction of the most superficial layers of the conjunctiva, which had become incorporated in the membranous structure; such membranes were more firmly adherent, and their removal was associated with conjunctival hæmorrhage. In other cases, again, the process had extended still more deeply, resulting in a more or less extensive necrosis of the tissues; such membranes were firmly adherent so that their removal would have entailed the display of an ulcerated surface.

The question of the relative frequency of glandular enlargement in the various infections presents a point of interest; such enlargement was usually observed in the severe cases of staphylococcal conjunctivitis, but was notably absent in the most virulent streptococcal cases.[9]

Corneal ulceration, although met with in all the types of infection, occurred in its severest and most intractable form in the streptococcal infections; indeed, there can be no doubt that the supervention of this complication in such infections renders the prognosis as to the preservation of the affected eye exceedingly grave, while the spread of the infection to the interior of the globe subsequent to perforation is liable to prove a menace to the actual life of the patient.

GROUP 6.—THE GONOCOCCUS.

This organism was obtained altogether 27 times; but this number cannot be taken as the proper proportion of its occurrence in the series, since many cases of ophthalmia of the newly born which presented themselves were not investigated. The majority of cases of gonorrhœal infection of the eyes in older children or adults are included. In 13 cases the gonococcus was associated with a diphtheroid bacillus. A white staphylococcus was present in two of these cases and in one other case, or in three cases altogether. The staphylococcus aureus was present twice, while the gonococcus was the only organism found in 11 cases. In only about one-fourth of the cases was a growth of the gonococcus obtained, the bacteriological diagnosis of the remainder resting with the examination of the films. No clinical difference in the severity of the case could be made out between those patients from whom a growth of the organism was obtained and in those from whom none was obtained; nor did the presence or absence of a diphtheroid bacillus appear to affect the clinical course. The two cases associated with aureus were both severe, in one case the affected eye being lost, while the other case was complicated by corneal ulceration. Of the three cases accompanied by albus two were of moderate severity and one was a mild affection. In five of the cases in older patients films were examined from the associated urethral or vaginal discharge and gonococci were found in each instance.

The question of the presence of coarsely granular eosinophile cells in the discharge and in the blood was particularly investigated. On the whole a slight but fairly constant increase in the eosinophile cells of the blood and of the pus was found to be present in the gonorrhœal infections; it was often, however, inconspicuous and occasionally absent, so that no reliance can be placed upon it in diagnosis. The presence of eosinophiles in the blood in the proportion of 2 or more per cent. was considered to constitute an eosinophilia.

---

[9] Cf. Jessop: Transactions of the Ophthalmological Society of the United Kingdom, vol. xxii.

The question of the existence of a gonorrhœal eosinophilia is considered by Cabot,[10] who considers an eosinophilia of 4·2 per cent. as within the normal limits, a number with which it is impossible to agree. In these cases no relation could be made out between the severity of the infection and the number of eosinophile cells present in either the discharge or the blood. Of these 27 cases 18 occurred in children under one month old and nine in older children or adults. The actual number of children *under one month old* examined in this series was 22. In 18 of these gonococci were present; in 4 they were found neither in the films after a prolonged search nor in the cultures. The organisms present in these four cases were a streptococcus twice, a white staphylococcus once, and a diphtheroid bacillus once.

GROUP 7.—THE DIPHTHERIA BACILLUS.

In 105 cases examined this organism was met with twice only, and since these cases represent only a small proportion of the total number of patients reviewed, the diphtheria bacillus would seem to be an unusual cause of conjunctivitis. In both these cases another organism was present—namely, in one instance the staphylococcus aureus and in the other the streptococcus pyogenes. Both patients were children suffering from a moderately severe type of conjunctivitis, which was, however, not clinically considered to be diphtheritic. A nasal discharge, from which the diphtheria bacillus was cultivated, was present in both cases and was probably the primary source of infection.

It is well known that diphtheroid bacilli are frequently present in the conjunctival sac, as also in the nasal mucous membrane, and that these organisms cannot be distinguished from the genuine Klebs-Löffler bacilli either morphologically or by their cultural appearances upon solid media. The most useful medium for distinguishing the two organisms is undoubtedly litmus dextrose broth, which is acidified by the diphtheria bacillus in 12 hours at 37° C. The diphtheroid bacilli met with in the eye affect dextrose so rarely that if a bacillus is present in the discharge and is found to acidify litmus dextrose in from 12 to 24 hours it is advisable to administer antidiphtheritic serum, whether the case clinically resembles diphtheritic conjunctivitis or not. By taking the initial culture on to a solid medium and by subculturing from that into dextrose a bacteriological diagnosis sufficient for practical purposes can if necessary be made in 24 hours. Since, however, diphtheroid bacilli are exceptionally met with which are capable of acidifying dextrose the diagnosis can be completed only by animal inoculation. In these cases two cubic centimetres of a thin suspension of the bacilli were injected subcutaneously into guinea-pigs, resulting in both instances in the death of the animal in from 30 to 36 hours with the ordinary post-mortem appearances of the disease; in one case the bacillus was recovered from the spleen.

The following are clinical notes of the two cases in which the Klebs-Löffler bacillus was found:—

CASE 14.—A male, aged one year and 11 months, I.P., S.T.H., Feb. 15th, 1907 (Mr. Lawford). Child ailing one week; croupy cough, no history of exposure to diphtheria. Right eye: both lids swollen; muco-purulent discharge; thin yellow membrane on conjunctiva of both lids, which was peeled off with difficulty, leaving a bleeding surface. Centre of cornea infiltrated. (When first seen, five days before admission, the membrane was limited to the lower lid, extending to the upper lid two days later; the cornea remained clear until the day before admission.) Left eye normal. Profuse nasal discharge and excoriation of left nostril. No membrane on tonsils. Temperature normal. Urine contained a strong trace of albumin. Klebs-Löffler bacillus and streptococcus pyogenes present in the conjunctival sac. On the first day after admission 8000 units, and on the third, fourth, and fifth days 4000 units of diphtheritic antitoxin were administered, the patient developing an antitoxin rash two days after the last injection; local treatment was limited to the use of antiseptic lotions, the use of nitrate of silver, which had been applied before admission to hospital, being discarded. The lids remained free from membrane after the fourth day and convalescence, although protracted, was satisfactory. Twelve days after admission a pustule was noted on the right cheek below the right eye. Cultures taken at about this date showed streptococci but no bacilli. The temperature on several occasions was as high as 100° F. but never rose above this, and the urine was free from albumin three weeks after admission. The patient left hospital on March 25th, the conjunctiva being then free from signs of inflammation and the cornea having healed. He was readmitted on May 13th, the right eye having been inflamed for a week and the condition being as follows. Right lids swollen; thin yellow absolutely adherent membrane on conjunctiva of both lids, which was considerably swollen; bulbar conjunctiva injected but very slightly swollen. Purulent discharge. Cornea not affected. Left eye normal. Right preauricular and submaxillary lymphatic glands enlarged. Urine contained no albumin. Temperature 101° F. The conjunctiva yielded a pure culture of streptococcus pyogenes; no bacilli were found either in culture or in film preparations. Four days later, under treatment with perchloride of mercury lotion, the condition showed considerable improvement, the membrane formation being less extensive. There was some superficial scarring of the conjunctiva.

We are much indebted to Mr. Lawford for his permission to publish this case.

The second case was of milder type with superficial membrane on the conjunctiva of both lower lids, enlarged preauricular glands, and thin nasal discharge. The fauces were normal. The patient recovered in 12 days without the use of antitoxin. There were no corneal ulceration, no albuminuria, and no subsequent loss of knee-jerks.

GROUP 8.—DIPHTHEROID BACILLUS.

In 60, or rather more than half of the cases examined, bacilli which morphologically resembled the diphtheria bacillus were present, either in the films, the cultures, or in both. In 49 of the cases other organisms were present in addition; in none of these cases was there any reason to suppose that the diphtheroid bacilli were the causative agents. In the remaining 11 cases, however, these bacilli were the only organisms discovered.

The term "diphtheroid bacillus" includes a variety of organisms, and a number of these have been investigated by Graham-Smith[11] and others with a view to their differentiation. The majority of those met with in the eye in this series, however, appeared to conform to the same type, while a few presented some cultural modifications; those which we have investigated from other parts of the body grew more abundantly in broth and more readily produced acid reaction in litmus dextrose broth. The name "diphtheroid bacillus" does not, in this account, include Hoffmann's bacillus, which is morphologically distinct from the Klebs-Löffler bacillus, and which was not met with in these cases. The frequent presence of these bacilli, both in the healthy and in the diseased eye, would seem to indicate for them a mainly saprophytic existence; they may frequently be seen in large numbers in a film within the epithelial cells and unaccompanied by evidence of inflammation.

The diphtheroid bacilli met with showed the following morphological and cultural characters. On agar a good growth, forming in from 12 to 24 hours small pin-point, rather opaque, colonies with slightly irregular margin and presenting a paler periphery with a ditch-like interval between centre and periphery. Films from these colonies show beaded bacilli with the typical arrangement of the diphtheria bacillus, large numbers having well-marked club-shaped ends. In films taken from the water of condensation masses of very beaded bacilli are present, many of them arranged in tight clumps, while streptococcal forms in chains of about eight to ten are not infrequent. The bacilli stain deeply by Gram's method, but their characters are best shown by Löffler's methylene blue; one culture which was kept for three months was found to have lost its property of retaining the stain by Gram's method. On blood agar and nasgar similar colonies are obtained. The bacillus grows well on gelatine at 22° C.; there is no liquefaction of the medium. In broth and in the various carbohydrate media no growth as a rule takes place, but the organisms maintain their existence. In litmus milk growth is often absent or is slight.

In the 11 cases in which diphtheroid bacilli alone were found the causative organism may have been overlooked, but in a few of these the features were clinically anomalous and more than one examination was made with identical results. In a high percentage of these cases the bacilli showed some cultural variations to the type usually observed and it is possible that some species of the diphtheroid bacilli may possess properties pathogenic to man. In a few instances animal inoculations were made but with negative results; the injections were in each case made subcutaneously into the legs of guinea-pigs.

CONCLUSIONS.

That both staphylococcus albus and staphylococcus aureus, as well as streptococci, are capable of exciting an acute conjunctival inflammation. That these organisms when they are present as the only pathogenic bacteria in an inflammatory conjunctival discharge should be considered as the causative agents. That these organisms give rise to a considerable percentage of all cases of acute conjunctivitis. That the severity of the type of inflammation they produce varies on the whole directly with the generally recognised pathogenicity of the members of the group, the most severe cases being associated with the streptococci and the least severe with the white staphylococci; but that the severity of the symptoms produced by any of the individual organisms may vary considerably with the idiosyncrasies of the patient. That there is reason to suppose that these bacteria, when associated with other pathogenic organisms, tend to increase the severity of the conjunctival inflammation. That the types of acute conjunctivitis due to these organisms, although presenting no pathognomonic features, are not infrequently suggestive of their etiology. That staphylococcal, as well as streptococcal, infection of the conjunctiva is liable to be associated with membrane formation. That conjunctivitis due to the diphtheria bacillus is uncommon and may be difficult to diagnose on clinical grounds. That diphtheroid bacilli are present in a high percentage of cases without appearing to influence the nature of the processes. It is probable that they represent more than one species and it is possible that some of these may be pathogenic to man; but there is no evidence that they may ever become transformed into the genuine diphtheria bacillus. That sporadic cases of pneumococcal conjunctivitis must be of rare occurrence in London, not a single case being met with in this series. Inasmuch as the diagnosis of this organism from a streptococcus may be a matter of great difficulty, its identification by film preparations only or by incomplete cultural investigations cannot be relied on; the mere appearance of encapsulation of the organisms in the films is most unreliable as a means of diagnosis. These observations agree with the investigations of others as to the rarity of organisms of the bacillus coli group as causes of acute conjunctivitis.

In conclusion, we have to thank the members of the staff of the Royal London Ophthalmic Hospital and of the Ophthalmic Department of St. Thomas's Hospital for permission to make use of the material from their cases. All the inoculation experiments were performed by Mr. L. S. Dudgeon at St. Thomas's Hospital and some of the organisms isolated were submitted to Gordon's tests by him. We are also indebted to him for his advice on many occasions. We have also to thank Mr. H. E. Gotelee, Mr. W. C. A. Ward, and other ophthalmic house surgeons at St. Thomas's Hospital for their assistance in obtaining the clinical notes of some of the cases.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES OF A CASE OF DISTAL LIGATURE OF THE COMMON CAROTID ARTERY FOR ANEURYSM.

BY J. CRAWFORD RENTON, M.D. EDIN.,
SURGEON AND LECTURER ON CLINICAL SURGERY, WESTERN INFIRMARY, GLASGOW; EXAMINER IN SURGERY AND CLINICAL SURGERY IN THE UNIVERSITY OF ABERDEEN.

THE patient, a female, aged 47 years, was sent to see me by Dr. J. Holms of Paisley in October, 1906 She was suffering from a pulsating swelling immediately above the right sterno-clavicular articulation and she complained of the throbbing and of a pain in the region of her heart giving rise from time to time to palpitation. On examination the tumour and its pulsation were distinctly visible and on palpation both were easily felt; the two radial pulses were equal in strength and character. Considering the above facts it was evident that she was suffering from an aneurysm of the first part of the right common carotid artery not involving the innominate or subclavian. I therefore advised that a distal ligature should be applied to the common carotid. Professor R. Stockman saw her in consultation and was satisfied that her general arterial condition was otherwise healthy. The operation was performed, a silk ligature being carried round the artery above the omohyoid. The wound healed by first intention; no headache was complained of, and the patient at the end of four weeks was allowed to lie on the sofa. On examination at the end of this time no pulsation was visible in the swelling and only moderate beating was noticed on palpation. Three months after the operation the patient was unfortunately in a tramcar collision, after which the pulsation increased for some weeks. This has now to a large extent subsided and the patient expresses herself as free from any discomfort.

Remarks.—Ever since Brasdor suggested and Wardrop carried out distal ligature of the common carotid in 1825 cases of aneurysm to which this method is suitable have occurred from time to time, but they are sufficiently rare to allow of the above case being recorded. The great improvement in the aneurysmal condition and the increased comfort which the patient now enjoys seem to justify the operation.

Four weeks after this case was under care Dr. Holms asked me to see another patient with an aneurysm exactly similar to the above. She was 74 years of age and had general arterial disease so that I did not advise operation. It is curious to have had the opportunity of seeing two such cases within six weeks, the more so that no parallel case has come before us for consideration for several years.

Glasgow.

A CASE OF FOREIGN BODY IN THE FEMALE BLADDER.

BY WILLIAM HOOK, L.S.A.

THE patient in the following case was a woman, aged 22 years, who was brought by her mother to my surgery on June 15th. I was informed that owing to difficulty in leaving her work for lavatory purposes her daughter had inserted a cork into her "front passage." An examination of the vagina showed that there was no foreign body there, so I assured her that it must have been expelled and as she no longer felt pain she went home. Returning, however, very shortly she said that she was sure the cork was still there. I then made an inspection, and finding the urethra very low and dilated without the slightest difficulty I passed my finger into the bladder and there came on the cork. About an hour later, having obtained the assistance of my friend, Mr. R. J. Heatly, of Stockwell-road, who put the girl under an anæsthetic, I made an attempt at removal but was unable to locate the foreign body. My friend, however, who has a long forefinger, quickly did so and after failing to grasp it with suitable forceps ultimately succeeded in manipulating it through the urethra. I saw the girl two days later and she then appeared none the worse for her foolish act. The cork measured an inch in length and half an inch in diameter.

Clapham, S.W.

A CASE OF PROLONGED RETENTION OF FOOD IN AN ŒSOPHAGEAL POUCH.

BY WILLIAM AYRES, M.D.DUB.

THE patient, who was a female, 38 years of age, suffering from pulmonary tuberculosis, sent for me as she was troubled with a severe cough. As there was a large cavity opposite the third and fourth ribs on the left side and as there was a large quantity of secretion this cough was naturally thought to be one of the ordinary concomitants of the condition present. A few days subsequent to my first attendance after a violent paroxysm of coughing a peculiar-looking yellow mass was expectorated. The cough was much relieved in a few days. The pathological report was as follows: "The substance expectorated one and a half inches long, five-eighths of an inch wide, is cheese; it must have been lodged in some fossa or in a pouched œsophagus formed by adhesion to a tubercular gland at the bifurcation of the trachea and after irritation from its presence or during an attack of coughing ejected." The patient disliked cheese; only twice during the year had she partaken of such an article of diet—namely, once during August and the last time on Dec. 26th. The substance was ejected on Feb. 5th, so that it must have lain in the pouch for at least six weeks without giving rise to any symptoms.

The points of interest are the size of the piece of cheese and the length of time it was in the pouch. The question will also arise, What, if any, are the powers of digestion possessed by the glands lining the œsophagus?

Brierley Hill.

Medical Societies.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Presidential Address.—A Lantern Demonstration on Some Points in Tropical Diseases.

THE first meeting of this society was held on June 26th, Sir PATRICK MANSON, the President, being in the chair.

The PRESIDENT, in delivering the opening address, said that one important object of the society was to bring together the men who were interesting themselves in tropical medicine with the idea that by so doing the subject itself would be advanced and the members benefited. With a view to securing these objects the society had been placed on a basis as broad as possible. Although domiciled in the metropolis it was open to any member of the profession, whether domiciled in London, Great Britain and Ireland, or abroad, and also to those followers of any science or profession capable of forwarding, directly or indirectly, the interests of tropical medicine. At one time the specialising of tropical medicine was looked on somewhat askance, and still more so the establishment of special schools for the teaching of tropical medicine. Doubtless the formation of the society would be regarded by some in a similar way, but in time the general body of the profession would become acquainted with its objects and work and, as had been the case with the special teaching of tropical medicine, the society would soon be tolerated and ultimately approved. The President then proceeded to compare the tropical medicine of the early "nineties" as represented by Davidson's "Hygiene and Diseases of Warm Climates," published in 1893, with the section on tropical diseases in the new edition of Allbutt's "System of Medicine." In Davidson's work the first chapter in the section on general diseases related to malaria. It was a carefully written article, embracing all the most important knowledge and views of the time; yet in that article there was not a single word on the mosquito as a carrier of malaria. In those days, although Laveran's great discovery had already been before the world 12 years, they had got no further than the conviction that air was a common medium of infection and there was still a lingering belief in the Hippocratic idea that the drinking of marshy water produced enlargement of the spleen. Now a large part of the tropical section of Allbutt's "System" was occupied with the part played by the mosquito in malaria. Everyone knew that the mosquito was the sole vector of malaria and an enormous literature had grown up around a discovery which had changed radically their views not only as regarded the etiology and prophylaxis of malaria, but had given a powerful stimulus to the study of the protozoa in general and also the rôle of insects in the transmission of disease germs. It could not be claimed that there had been much material advance in regard to cholera, leprosy, and beri-beri; but as regarded negro lethargy or the sleeping sickness it might be claimed truly that the whole subject, alike as regarded etiology, symptoms, diagnosis, and treatment, had been completely revolutionised and placed on a sound basis. They now knew that the sleeping sickness was the terminal phase of a trypanosoma infection, a type of disease hitherto unrecognised in human pathology, that the immediate cause of the sleeping symptom was an infiltration of the lymphatic spaces of the brain with certain small mononuclear cells, that the disease was conveyed by the tsetse fly, and that it was amenable to some extent to arsenic, mercury, and certain dyes, all absolutely of recent discovery. The tropical fluxes—diarrhœa and dysenteries—in the aggregate constituted the most important department of tropical medicine, but unfortunately they were still, both as regarded etiology and treatment, in an unsatisfactory state. It was true that the amœba was creeping into favour and that they had got the length of recognising a bacillary dysentery, but the amœba and the bacillus dysenteriæ did not cover the entire field and unfortunately the knowledge of their existence had not materially strengthened the power of treatment. The numerous additions to tropical helminthology were important. Chief among these was Looss's discovery that the larval ankylostome obtained access to the intestinal canal by penetrating the skin or the surface of the body—a discovery suggesting possibilities which had to be reckoned when they studied the route by which access was obtained to the human host. The modern text-books must have chapters on spirillosis, seeing that the term relapsing fever which Murchison and others used and which Carter also used in his studies in India covered not one but a number of infections, spread probably by a corresponding number of previously unsuspected ticks or other blood-suckers. Then the tropical pathologist must take cognisance of a number of diseases of the lower animals, important in themselves, but more important in illustrating principles applicable to human pathology, especially tropical pathology. The study of the anthropode and correlated disease blood-suckers had grown to be so vast a subject that for its proper appreciation special studies had to be made and its teaching relegated to special men. In Davidson's day a single culex was all that they had to study, but nowadays they had to know something about nearly 600 species of mosquitoes and so, in a less degree, with the ticks, the tsetse flies, and several other though less important blood-suckers. He might enumerate many other discoveries and changes, but those he had alluded to sufficed to show that within the last 13 or 14 years the progress in tropical medicine had been remarkable. Not only had recent discovery widened their horizon, but many additional workers were now in the field and hitherto untrodden departments of natural science having a bearing on tropical pathology had been annexed by the tropical pathologist. The multiplication of workers was extraordinary and doubtless was accounted for by the establishment of the several tropical schools in Great Britain and elsewhere, and not least by the sympathy and active encouragement that research in tropical pathology had received at the hands of the British Government. Time was when with justice they could reproach their rulers for indifference in that matter; nowadays quite a different feeling obtained in official circles, and instead of being repressed and cold-shouldered the investigator in tropical pathology was encouraged in every possible way by the British Government and its officers. Other Governments, too, had ceased to be indifferent; some were actively sympathetic. The interest which the British Government had shown in sleeping sickness promised well. The fact that His Majesty's Government had called a conference of the foreign Powers to discuss that subject from an international point of view showed that they were entering on a new era as regarded the Governmental element in the study of tropical disease. It might be that that sleeping sickness conference was but the prelude to similar discussions and international agreements on the subject of other important tropical diseases, a matter of more importance than at the first glance it might appear to be. All over the British tropical possessions laboratories were being established for the special investigation of tropical disease and for the assistance of the tropical practitioner. These laboratories had just began to bear fruit, and he had not the slightest doubt that ten years hence they would have important discoveries as well as an enormous accumulation of important data as a result of that enlightened policy. The rôle of the society was to try to bring them abreast of what was being done by that army of workers, so that those who had to teach in that country and those who went abroad to practise or to investigate should be thoroughly abreast of what had been done and of what was being done, so as to be in the best position to do full justice to tropical patients and to tropical diseases and hygiene and to lend a hand in advancing the subject.

Dr. C. W. DANIELS of the London School of Tropical Medicine gave a lantern demonstration on Some Points in Tropical Diseases. He commenced with diseases such as yaws, not directly fatal, and ended with such serious affections as beri-beri and sleeping sickness; he emphasised the importance of preventive measures in tropical diseases.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on June 18th, when a discussion took place on Opinion and Fact in Medical Evidence; Mr. Walter Schröder *presided.*—Dr. C. H. Wise, in opening the discussion, commented upon the sharp distinction which is often drawn in practice and in books on evidence between "opinion" and "fact." He said: It is laid down that "a witness should state facts only. His mere opinion is no evidence." Explanations of facts are rejected as "mere opinion" and it is often hinted that medical men are prone to confuse opinion and fact, to obtrude their opinions instead of confining themselves to the plain statement of observed facts. Three propositions were laid down for discussion: 1. The opinions of a medical witness on observed facts are often more valuable than the mere narration of the facts themselves. A matter of fact, as presented in evidence, may be defined as something of which we obtain a conviction from our internal consciousness or from the use of our senses, something seen, heard, or felt. Medical facts seldom can be produced in any court as primary evidence to speak for themselves. General propositions, being facts, such as the circulation of the blood or mathematical deductions, are excluded. Facts are proved by the testimony of percipient witnesses. When a fact is doubted on reasonable grounds or when a statement is a deduction from observed facts it becomes matter of opinion. For present purposes, a matter of opinion is a conclusion or judgment which is arrived at by comparisons of present observations with recollections of similar observations in like conditions and a balancing of the relative importance of resemblances and differences. Regarded thus, more so-called "fact" is really opinion than we usually realise. For all evidence of fact is really testimony to judgment on observed phenomena, it is something more than a description of the impressions made on our senses and therefore implies a theory or explanation of them. This judgment is generally so simple as to be unconscious and the interpretation of the appearances is matter of general agreement. Similarly the simplest medical evidence is of more value than the bare facts, which testified to alone are unintelligible. If merely the facts that are observed, say, in the case of a broken bone, are given in evidence an ordinary tribunal would fail utterly to appreciate their importance or their meaning unless the medical deductions were also stated. Even skiagrams, which have thrown such a flood of light on such cases, need the explanation and judgment of the skilled observer. 2. In medical evidence a clear line between opinion and fact cannot be drawn. This is one of the chief sources of the weakening of such evidence and yet it is strictly comparable with similar gradations in ordinary testimony to fact. Eye-witnesses may differ as to observed facts. Their perception may be modified by distance, by intervening objects, by dim light, by imperfect sight, by inattention, and by all these in any degree, so there may arise all gradations between what may be fairly called an accurate testimony to what existed or happened, and what is mere guessing from imperfect impressions. Most medical evidence is subject to similar modifications. It is in some cases an accurate conclusion arrived at from observations accurately made, and ranges from almost absolute demonstration to great uncertainty. The varying degrees of the faculty of observation, of development of the *tactus eruditus*, added to the obscurities of the subject, either innate or from surrounding circumstances, lead to doubt and difference. A broken bone may present every gradation from a protrusion of the broken end through the skin, a "fact" manifest and unmistakeable, to the obscure fracture that defies accurate recognition even with the aid of the x rays. This uncertainty is aggravated in some cases by the mutability of the subject matter. Disease is not, as it is commonly regarded, a definite entity, but is the manifestation of the struggle between microbic invasion or injury and the vis medicatrix of nature, in which the more or less complete victory of either combatant results in some one of the protean disorders which we label as ailments. As instance, scarlet fever with its varieties of epidemic type and gradations in unbroken series from mere slight sore throat to the most malignant forms. 3. Medical opinions are often valuable and conclusive, even when they cannot be supported upon cross-examination by the direct evidence of observed facts. This support should, of course, be possible, but its absence is not destructive of the value of the evidence. Experience in medical practice leads to the possibility of a power of recognition, an intuition that may fairly be compared to the method whereby personal identification is effected, although the minute facts leading to it cannot be detailed. A man may be certain in recognition of his friends and completely unable to explain by what facts he does so. The policeman may be quite correct in saying that a man was "drunk," although he is distressingly puzzled when cross-examined as to the actual details which have led him to that opinion. In the same way medical opinion may be a recognition based upon unconscious observations and judgments upon facts which, though undoubtedly present, are intangible and indefinable.—Dr. Charles Mercier suggested that variations in the statements of observed facts were often due to an absence of the power of verbal description. The state of another person's mind could never be known; all that was known was what he said, what he did, how he looked. As a matter of fact, all testimony which was outside our own minds was a matter of opinion.—Earl Russell thought differences resulted from the fact that the standards of comparison varied. It was of little use to state the whole truth in technical terms if the conclusion was not also included. When an opinion pure and simple was expressed the facts which led to that opinion should be extracted.—Dr. F. J. Wethered held that in arriving at a prognosis opinion was distinct from, though founded on, fact.—Dr. Stanley Melville, Dr. Albert Wilson, and Dr. Alexander Ambrose also spoke.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The final meeting of this society was held on June 26th, when it was formally dissolved and merged into the dermatological section of the Royal Society of Medicine. The President, Dr. Leslie Roberts, was in the chair.—Dr. A. Eddowes showed: 1. A girl, aged 16 years, with a Chronic Pruriginous Eczema affecting the lower limbs chiefly of 11 years' duration. 2. A woman, aged 56 years, with an Infiltrated Patch upon the left temple which had been present for 16 months. The centre was atrophic and the margins were raised and reddened. The diagnosis lay between a tertiary syphilide and a rodent ulcer. 3. A photograph of a case of Malignant Syphilis in a young woman in whom there was great phagedænic ulceration of the nose.—Mr. T. J. P. Hartigan showed: 1. A man, aged 56 years, who had a Rodent Ulcer which the exhibitor had treated with radium. The scar of the original ulcer was now plainly visible, the result being eminently satisfactory. Unfortunately, a fresh nodule had just begun to appear upon the nose, unconnected, however, with the scar. 2. A little girl, aged four years, who had had a Hairy Mole upon the Right Cheek similarly treated. 3. A man, aged 68 years, with Lupus Erythematosus of the Scalp of 40 years' duration. The disease was of the atrophic type and the general health of the patient was quite unimpaired. 4. The daughter of the last patient who had been more or less bald since the age of ten years. When five years old she had had some scalp affection and now three months ago, after a confinement, she began to suffer from an acute attack of what appeared to be eczema of the scalp. The diagnosis was far from obvious, some of the members suggesting that the source of the whole trouble might have been a favus, while others considered that lupus erythematosus was not out of the question.—Mr. Spencer Hurlbutt showed a little boy, aged four years, with a Psoriasiform Patch of the size of a crown-piece upon the abdomen, which began as small ringed spots four months ago and was considered to be ringworm. It did not respond to treatment but had continued to spread. The question now was whether the lesion might not be tuberculous in character.—Dr. G. Norman Meachen showed a male infant, aged eight months, with a Bromide Eruption, affecting the vaccination scars primarily as well as appearing in the form of small raised plaques upon the thigh. The source of the drug had not yet been successfully traced.—Dr. T. D. Savill showed: 1. A young woman, aged 25 years, with Epidermolysis Bullosa Hereditaria, affecting chiefly the legs. All the nails of the hands and feet were diseased. She had improved much under the influence of small doses of ergot, administered twice a day. 2. A case of Exfoliation of the Palms in a young woman, aged 21 years, who had suffered in this manner for three successive summers. There was some hyperidrosis.

MILLER HOSPITAL.—A festival dinner in aid of the funds of the Miller Hospital and Royal Kent Dispensary, Greenwich, was held on June 27th at De Keyser's Royal Hotel, Victoria Embankment. The Lord Mayor of London presided. In proposing the toast of the evening, "Success to the Miller Hospital," he said that relief had been provided for the sick and necessitous poor of Greenwich by this institution for 124 years. The annual expenditure was £4500, of which only £450 was assured. During the past year 285 in-patients had been received and 18,624 out-patients treated, 600 patients visited at their homes, and 560 maternity cases attended. If a suitable site could be found it was thought desirable to extend the hospital but, of course, money would be required to do this. In the course of the evening subscriptions to the amount of £1200 were announced.

Reviews and Notices of Books.

A Text-book of the Practice of Medicine for Students and Practitioners. By HOBART AMORY HARE, M.D., B Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Second edition. Illustrated. London: Henry Kimpton. 1907. Pp. 1132. Price 21*s*.

THE first edition of this work was published in 1905 and the fact that so short a time has elapsed before a second edition has been found necessary is sufficient proof that the efforts of the author have met with the recognition which they deserve. In our review of the former edition[1] we expressed the favourable opinion which we had formed of the book as a whole and we also explained its plan and scope. We need not therefore dwell at length on the general plan of this text-book but will merely indicate the changes and additions which have been made in the present volume. These have involved but little alteration in the size of the work (a difference of 13 pages only), but every care has been taken to embody the latest views which have received general acceptance as being scientifically and clinically correct. Dr. Hare has shown a practical judgment in coming to the conclusion that the needs of the student and practitioner would be most satisfactorily met by excluding statements open to criticism and presenting facts which would prove useful in practice. Amongst the additions in this edition we notice some remarks on myelopathic albumosuria. The reference to this interesting condition is, however, very brief and only occupies ten lines. It is to be regretted that the valuable observations on this subject by Dr. C. W. Paget Moffatt and other observers have not been more fully referred to.

The subject of malarial fever is no longer placed amongst the "Infectious Diseases" but is considered in the section on "Diseases Due to Animal Parasites." No alteration has been made in the definition of the disease and although on etiological grounds there may be justification for this change in classification, yet for purposes of convenience the older plan is to be preferred. We may also remark that in the last edition of "The Nomenclature of Diseases," drawn up by a joint committee appointed by the Royal College of Physicians of London, "malaria" is still considered an "infective disease." The same alteration has been made in respect to kala-azar (this again being out of accord with the opinion of the committee just named). The results of Leishman's researches as to the etiology of this disease are duly described.

In the section on "Special Forms of Neuritis" a brief description is given of "obstetrical or birth palsy"—an affection of the nerves of the brachial plexus occurring after difficult and protracted labours, especially in cases of breech presentation.

It is somewhat disappointing to find that in the portions of the work devoted to treatment the power of description and lucidity of expression so characteristic of the author's manner of writing are not maintained at their usual level. His directions as to the treatment of any particular disease, as a rule, lack that detail which is so useful to a practitioner when seeking help in the therapeutics of a difficult case. The methods used in many instances differ from those usually employed in this country. Generally speaking that is of advantage as much may be learned from the experience of those trained in different schools. There are also some noteworthy omissions of drugs frequently adopted by English practitioners. For instance, stramonium is not mentioned by name with regard to the treatment of asthma, although we presume that Dr. Hare includes it under the heading of "Belladonna and its Sister Drugs" Still, no proper directions are given for its employment. Want of detail is again to be noticed in the description of the treatment of pulmonary tuberculosis on sanatorium lines.

Taking the work as a whole, however, we can recommend it as one containing a vast amount of information useful to students and practitioners. The sections on tropical diseases may be especially mentioned, and the text-book will be useful to medical men practising in countries in which such diseases are likely to be met with.

Annual Report of the Sanitary Commissioner with the Government of India for 1905, with Appendices and Returns of Sickness and Mortality among European Troops, Native Troops, and Prisoners in India for the Year 1905. Calcutta: Office of the Superintendent of Government Printing. 1906. Pp. 143. Price Rs. 3 or 4*s*. 6*d*.

THE report before us contains, as in previous years, the facts relating to health concerning the European army of India, the native army of India, and the gaols of India, the vital statistics of the general population, the history of the chief diseases amongst the general population, and the general history of vaccination in India, and concludes with some general remarks on various subjects. As regards the meteorology of the year 1905 this was characterised by the severity and persistency of the cold weather and the lateness and scantiness of the monsoon rains, especially in the north-west, and the consequent high temperature. With regard to the health of the European army the admissions for venereal disease head the list, although the rate was considerably lower than in previous years, being 153·7 per mille, as contrasted with 198·5 in 1904 and 385·5 for the decennium. Malarial and enteric fevers likewise gave a diminished ratio. The main causes of death were enteric fever and hepatic abscess, these diseases accounting for 29·7, and 11·7 per cent. of the total mortality respectively. The northern command was the healthiest as regards the numbers of those constantly sick and as regards the mortality-rate.

In the remarks on the various diseases we find a review of the different methods of prophylaxis against malaria, and the opinion is given that for practical prevention the methods of Koch and Morgenroth are probably the best—viz., the prescribing of 15 grains of quinine every ninth or tenth day, or on two consecutive days each week, whereby the drug is in such concentration that the parasites are quickly and easily killed, being still in those stages of development which are most susceptible to its action. The method of Plehn, which consists in the giving of eight grains every fifth day, is probably the least satisfactory. Attention is likewise drawn to the importance of recognising the increase in the relative number of large mononuclear leucocytes in the diagnosis of malaria. The x rays are noted as having no effect on the course of an attack or on the parasites but as having a favourable action on the chronic large spleen. With respect to the various forms of malaria noted, of 8106 cases, 73·78 per cent. were cases of benign tertian, 1·28 per cent. of quartan, 5·00 per cent. of malignant tertian, 0·38 per cent. of malarial cachexia, and 19·56 per cent. were returned as undifferentiated, showing, as is always the case, the relative rarity of the quartan form. With respect to treatment, it was found that quinine when in compressed form frequently passed unchanged through the system, whilst if the drug were administered by intramuscular or hypodermic injection the action was most rapid and powerful. We are glad to see that the authorities are making use of all the measures noted for the prevention of malaria; the patients are isolated wherever possible, wire gauze to the doors of the hospitals and mosquito curtains being used. Four cases of Malta fever were reported for the year, with no deaths, as contrasted with six admissions with three deaths in 1904.

---

[1] THE LANCET, March 10th, 1906, p. 672.

An excellent summary of the recent investigations as regards enteric fever is given; indeed, the section dealing with this all-important disease in India is one of the most valuable in the report and well repays perusal. Here we find the work of Krencker on the biology of the coli-typhoid group of micro-organisms first referred to; next, the results are alluded to of the campaign against endemic typhoid fever on the south-west frontier of Germany and note is made of the fact that the healthy, or at least the non-specifically sick, can harbour typhoid bacilli and secrete them to the danger of the public. The advantage of the method of blood culture for the early, rapid, and comparatively easy diagnosis of typhoid fever is insisted on. Respecting the vitality of the bacillus typhosus in water, it is shown to be but a short-lived organism in water under natural conditions. The infection by milk and other foods and the infection by contact, immediate or mediate, receive due attention. The part that infected dust and flies play in the propagation of the disease is insisted on, after which the paratyphoid bacilli receive attention. The necessary preventive measures are noted, whilst with regard to inoculation we observe with satisfaction that this practice has resulted in a substantial reduction in the incidence of, and death-rate from, enteric fever amongst the inoculated.

In the section on general remarks we find the work of the Mediterranean Fever Commission, carried on under the supervision of an advisory committee of the Royal Society, duly acknowledged. The work done by the Pasteur Institute at Kasauli is chronicled and due mention is made of the King Institute of Preventive Medicine at Guindy and of the Pasteur Institute for Southern India at Coonoor. We are glad to note that medical officers of both the Services are allowed to proceed to a laboratory for a period of from three to six months for the purpose of prosecuting research already commenced, or for instruction in technique, provided local arrangements can be made for the conduct of routine duties during their absence. In addition to the work at the bacteriological laboratories special inquiries have been commenced with reference to typhoid fever in India, dysentery in gaols and lunatic asylums, and malaria in the Presidency division of Bengal, and the inquiry into the etiology of kala azar has been continued. An important investigation is taking place on the nature of the dysentery that is the most known cause of mortality in Indian prisons, by Captain W. C. H. Forster, I.M.S., whose results will, it is hoped, add to the existing knowledge of one of the most fatal of tropical diseases. This valuable report finally closes with the various appendices relating to meteorology, admission-rates, and so on, of the different diseases amongst the European and native troops, and amongst the gaol population.

The Drink Problem in its Medico-Sociological Aspects. By Fourteen Medical Authorities. Edited by T. N. KELYNACK, M.D. Vict., F.R.C.P. Lond., Honorary Secretary of the Society for the Study of Inebriety, &c. London: Methuen and Co. 1907. Price 7*s.* 6*d.* net.

OF the importance to the community of a careful study of the problem of alcoholic indulgence and of the remedies which are proposed for the evil there can be no possible question. The present volume of 300 pages contains a series of essays by different authors on various aspects of the drink problem. "Each contributor has been allowed a free hand in the presentation of the particular subject allotted and each writer is responsible only for the chapter contributed." So speaks the editor in the preface and thereby lifts a load of responsibility off his own shoulders. He himself contributes an introduction, which is followed by an article by Dr. Harry Campbell on the historical side of the question and on the mode in which habits of excess are initiated. The psychology of the alcoholic subject is dealt with by Dr. T. Claye Shaw and the relation of drink to mental disease by Dr. T. B. Hyslop. Pathology is represented by Professor G. Sims Woodhead. Medico-legal points are discussed by Dr. Stanley B. Atkinson and the public health aspects by Dr. Arthur Newsholme. Mr. W. McAdam Eccles contributes a chapter on Alcohol in Relation to Life Insurance and Dr. Mary A. D. Scharlieb points out its special bearing on the social condition of women and children. Crime and pauperism as produced by alcoholic indulgence are discussed respectively by Dr. W. C. Sullivan and Dr. Ralph H. Crowley; its share in the production of national deterioration is indicated by Dr. Robert Jones. Methods to be adopted for the teaching of temperance form the subject allotted to Dr. E. Claude Taylor, while Dr. V. H. Rutherford, M.P., gives his views on the legislative measures that are required to combat the evil. The articles are necessarily of unequal merit. The most striking is that by Mrs. Scharlieb which breathes a spirit of broadmindedness and charity conspicuously absent from too much of the writing on the subject of alcoholism. The chapter on legislative measures for the control of the vice is disappointing, the writer even suggesting, apparently, that temperance is impossible so long as there is private ownership of land, whilst most of the paper is full of whirling words rather than of discussion of what is practicable. The editor's final contribution on the Arrest of Alcoholism serves to some extent to make up for the defects of the preceding oration. We do not find any novel light thrown on the problem of alcoholism in this volume. It is, however, a compendium of most of the facts known as to the habit and should form a valuable work of reference for those who are called upon to speak or to write on the subject. References are given to other works on alcoholism from which material is derived.

LIBRARY TABLE.

A Health Reader. By C. E. SHELLY, M.D. Cantab., and E. STENHOUSE, B.Sc. Book II. London: Macmillan and Co. Pp. 96. 1*s.* 4*d.* net.—This book, like its predecessor, is the result of the serious attention that is being given to the teaching of the elementary facts of physiology and hygiene to school children. It is intended for pupils of from ten to 12 years of age, and the simplicity of diction is well suited for such little ones. We are able to give a considerable measure of praise to the body of the book. Anyone who has had the task of teaching medical subjects to a non-scientific audience knows well the difficulty of steering the middle course between explaining too little and attempting to explain too much. This difficulty must be intensified in teaching the elements of such subjects to young children to whom life is still something of a wonderland and who have no inherent conception of the idea of natural law; indeed, to some people it may be a matter of doubt as to whether physiology can be really profitably taught to children quite ignorant of the simplest facts of chemistry and physics, and there is no doubt that lessons such as these would come more readily to a class having some such instruction. The authors, however, have contented themselves with such simple physiological explanations as are necessary for the teaching of the first principles of hygiene and in this they have been so successful that their book will be of real service to those teachers who are empowered to impart such instruction. The pictures are well planned to catch a child's attention.

A Monograph of the Culicidæ or Mosquitoes. Mainly compiled from Collections received at the British Museum. By FRED. V. THEOBALD, M.A. Vol. IV. With 16 plates. London:

Printed by order of the trustees. Pp. 639. Price £1 12s. 6d. net.—The monographs issued under the ægis of the national museum at South Kensington are habitually worthy of the authority of that distinguished institution, and the volume before us is no exception to the rule. As Sir E. Ray Lankester states in his preface, the publication of the first two volumes of the present series in 1901, which formed the first systematic treatise on the Culicidæ, together with the sending of requests to all parts of the world for specimens, has resulted in a rapid increase of knowledge of this family. The rapidity with which the knowledge has been increased is shown by the fact that since the first supplementary volume (Vol. III. of the series) went to press in 1903 no less than 160 new species have been described. The present volume is based on an examination of some half of the 12,000 specimens received at the Museum since 1903. The British Museum trustees have recognised to the full the importance of investigating the various species of blood-sucking insects which may become the carriers of pathogenic parasites and they desire "to obtain as complete collections as possible of blood-sucking insects and arachnids from all parts of the world, with a view to the production of further monographs on such flies, fleas, bugs, lice, ticks, and acarids, as may be the agents in the spread of disease." The director of the Natural History Department invites the sending of further collections of blood-sucking insects and coloured drawings or notes upon their habits to South Kensington. The present volume is a monument of careful study and observation and the illustrations are worthy of the text. The author describes 17 anophelines as certain carriers of malarial parasites and 55 as possible carriers; eight species are responsible for the dissemination of filariasis, and one each for yellow fever and dengue. Mr. Theobald very rightly deprecates the complication of an already too confused nomenclature by the naming of new species on the sole authority of local colour variations. The work is to be completed in a further volume. It is good to see such a monograph issued from a London press as will be indispensable to foreign workers in an important field.

The American Medical Directory. Chicago: Published under the official auspices of the American Medical Association. Pp. 1422. Price 33s. net.—The compilation of a directory dealing with so large a body of men as the medical profession must afford a task of great labour in so compact a country as our own; the performance of such a duty for so scattered an area as the United States is a task that probably only those diligent persons who have been engaged upon it can adequately appreciate. The present work contains, in addition to the official list of legally qualified practitioners in the United States, complete information regarding the laws regulating the practice of medicine and particulars as to the constitution of the State boards of health and the medical examining boards and colleges. It is somewhat curious to British eyes to see certain of the names followed by initials which indicate that their owners belong to the cult of "Homœopaths" or "Eclectics" respectively; there is an archaic flavour about the latter title which is at pleasing variance with our notions of American cast-iron modernity. The book is well printed and we do not doubt will form an indispensable work of reference to all who are interested in American medicine. The information concerning the laws controlling practice in the individual States is very valuable.

MAGAZINES AND JOURNALS.

The Edinburgh Medical Journal.—A good deal of attention has recently been directed to the question as to the value of preparations of formic acid in the treatment of disease. An article in the June number of this magazine, written by Dr. Claude B. Ker and Dr. David H. Crowe, on the use of formic acid in diphtheria, concludes with the expression of opinion that the results obtained in the direction of warding off cardiac failure are distinctly encouraging. Mr. W. H. Battle writes on traumatic rupture of the intestine and insists on the importance of early operation; and Mr. Alexander Don emphasises the value of x ray examination in the diagnosis of tuberculosis of bones. An interesting note upon the application of Bier's treatment by passive congestion to acute inflammations, written by Mr. D. M. Barcroft, calls attention to the value of a procedure that is perhaps not sufficiently practised in this country: in gonorrhœal affections of joints it would appear to be almost a specific, and it is available in many other conditions.

The Scottish Medical and Surgical Journal.—The June number of this journal opens with an article by Dr. C. J. Lewis upon the influence of meteorological conditions on the distribution of bacteria in urban atmospheres. The author shows the value of rain in purifying the air and also the contrary influence of high atmospheric pressure in increasing the number of organisms present. Dr. Claude B. Ker writes in praise of intubation in diphtheria, especially if used in connexion with nasal feeding, and Dr. W. T. Ritchie describes and discusses the various forms in which an extra systole of the heart may take place.

The Dublin Journal of Medical Science.—Dr. G. A. Gibson's learned account of our debt to Ireland in the study of the circulation is concluded in the June number. The present instalment deals with the importance of physiological incompetence of the right auriculo-ventricular valve and with some modern studies on the subject of heart block. Dr. W. G. Harnett writes on early diagnosis of perforation of a gastric ulcer and Dr. C. H. McComas notes some practical points in the study of disease in infants.

The Medical Chronicle.—Two articles of more than ordinary interest appear in the June number of this magazine. Dr. W. B. Heywood contributes an abstract of a thesis dealing with the subject of albuminuria in adolescents. He analyses much recent literature and records some observations of his own on the albuminuria which follows scarlet fever. He concludes that about 50 per cent. of children who suffer from this disease pass urine containing some albumin and that this condition may persist for some years. Most of the cases seem to recover ultimately. Dr. Frank E. Tylecote discusses the symptoms of meningism or transient meningeal irritation and its diagnosis from meningitis proper. He also considers the information to be obtained from lumbar puncture in such cases and the causes of improvement following this procedure, but comes to no certain conclusion on this last point. Mr. Philip B. Wrigley records a case of strangulation of the vermiform appendix in a hernial sac.

New Inventions.

MODIFICATION OF BARTRINA'S PROSTATIC CATHETER.

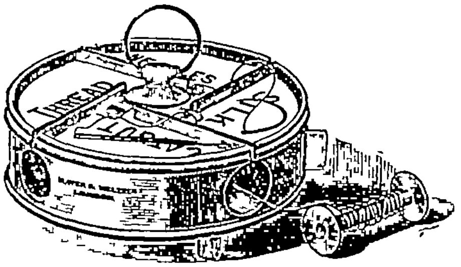
HAVING a case of left lateral hypertrophy of the prostate necessitating the routine use of a catheter, and finding that ordinary catheters, à boule and coudé, were passed with difficulty and were apt to draw blood, I tried the catheter devised for such cases by Dr. J. M. Bartrina of Madrid, an account of which is given in THE LANCET of May 16th, 1903. This instrument is oval in section, with the long diameter vertical, O, and the beak is curved on the *edge*. I did not find this catheter to pass more easily than the others and noticed that immediately it entered the urethra it turned in my hand to the extent of a quarter of a circle, thus deflecting the beak to the same extent. The cause of this deflection is obvious when one considers the anatomical fact that, although the meatus urinarius is a vertical slit, |, the urethra itself in its entire length, including the prostatic portion, is a tube having its walls in contact and presenting on section a transverse slit, —, the prostatic portion being somewhat curved with the convexity upward, ⌒. Believing, however, that an oval instrument might well possess an advantage over a round one, provided the long diameter of the oval was transverse instead of vertical, I had catheters specially made for me in France by the courtesy of Messrs. Allen and Hanburys. On trying one of these in my case I found it was passed with perfect ease, both by myself and my patient who volunteered the opinion that he had never passed a catheter so easily and comfortably, nor did it cause bleeding. The catheter, thus modified, is of elastic gum, silk web, coudé, oval, flattened transversely, ○, with the beak curved on the *flat*.

It may be had in 11 sizes (12–22) from Messrs. Allen and Hanburys, Wigmore-street, W.

Driffield, East Yorks. A. T. Brand, M.D., C.M. Aberd.

AN APPARATUS FOR STERILISING SUTURES, LIGATURES, AND NEEDLES.

The apparatus shown in the accompanying illustration was exhibited at the Australasian Medical Congress held in Adelaide in October, 1906, and attracted favourable notice. My aim has been to design an apparatus in which the sutures, ligatures, and needles could be sterilised simultaneously either in boiling water or by steam, so as to be fit and ready for use in the surgeon's instrument tray and be handled by him only. The apparatus has been used by me at all my operations during the last six months and it fulfils its purpose admirably. The structure consists of two parts, an outer part and an inner part. The outer part is a cylindrical copper dish six inches in diameter and one and three-quarter inches deep. The bottom is perforated by a small central hole and three slots. Four holes, three quarters of an inch in diameter and equidistant, are cut in the side of the can. From the centre of the upper border of each of these holes a slot one-eighth of an inch wide is cut and extends through the upper edge of the side of the can. The inner part is also a flat cylinder of copper. Attached to the bottom are three legs half an inch in length, and these extend through the slots cut in the floor of the outer part. The top is divided into four compartments into which exactly fit four pieces of white opal glass. These are held in place by a central screw with a ring attached. The sides of both parts are perforated by four circular holes three-quarters of an inch in diameter. From these openings four small cylinders, two and a half inches long and three-quarters of an inch in diameter, extend to the centre of the inner part. The sides of these cylinders are so bent that they are brought out through the top of the inner part and form four radiating slots, thus dividing the top into the four compartments previously mentioned. By means of a small flange the outer part can be made to revolve round the inner for a distance of three-quarters of an inch, the legs on the inner, which work in the slots on the bottom of the outer, acting as stops. Thus, when the lateral openings of both parts coincide the small cylinders are open and when the outer is made to revolve round the inner they are shut.



The apparatus is used in the following way. The small cylinders being open, metal or glass reels on which the ligature and suture material is wound are inserted into them, the loose end of the material (silk, thread, &c.) is brought through the slot in the side of the outer part and thus comes to lie in the long narrow slot in the top of the inner. The loose end is then threaded on any needle the surgeon wishes and the needle laid down in one of the compartments. The thread on each reel may be similarly threaded. Usually, however, I only have two of the needles threaded and extra needles are placed in one of the compartments. The other two reels are then used for ligatures only. The ends of the cylinders are now closed and the apparatus is ready for sterilising. This can be done by boiling it or putting it in a small kettle and sterilising it by steam. After this it is placed in the instrument tray. Should the surgeon use catgut, reels with this material wound on them are now inserted into the cylinders, for, of course, catgut does not stand boiling or steam sterilisation. Whatever material is used, the reels revolve easily in the cylinders and the ligatures, sutures, &c., are cut off by the surgeon as he requires them. It is often useful to have two or three needles on one thread. The needle closest to the loose end is held by its eye between the right forefinger and thumb to prevent the thread slipping out, which is then drawn through the eyes of the remaining needles held between the left forefinger and thumb and cut off at the required length. These remain threaded for the next suture that may be required. My needles are always kept in lysol between operations and do not rust when sterilised in this apparatus. I do not allow instruments, needles, ligatures, &c., to be touched by anyone but myself or my assistant. By means of this apparatus all ligatures, sutures, and needles are ready for use when I start to operate, much time is saved, and an additional pair of hands and a source of infection are dispensed with. It can be made of any size and, if desired, the number of small cylinders and compartments increased. The opal glass is marked "silk," "catgut," "needles," &c., to enable each kind of material to be kept in its own proper compartment. The apparatus is nickel-plated throughout and is easily taken to pieces and cleaned.

Messrs. Meyer and Meltzer, of London and Melbourne, and Messrs. Fischer, of Adelaide, have carried out my design admirably.

THE LANCET, *SATURDAY*, July 4th, 1829.

PRESERVATION OF THE ERGOT OF RYE.

To the Editor of The Lancet.

Sir,—If a small piece of camphor be put into a bottle, containing ergot of rye, reduced to a fine powder, the peculiar properties of this invaluable remedy will be retained, unimpaired, for a considerable length of time, two or three years at least.

As I am not aware that this fact is generally known, I shall feel obliged by your honouring it with a place in the columns of your very valuable and talented Journal.

I remain, Sir,
Your obedient Servant,
S. F. G.

NEW FOOD AT THE FRENCH HOSPITALS.

The use of gelatine from bones is becoming very general in the French hospitals as an article of diet. In La Charité, upwards of a thousand rations a day are produced by means of a steam apparatus. The patients are said to approve of it much, as it is made very pure, and may be flavoured in any way that is wished.—*Lit. Gaz.*

Death from Electric Shock.—The *Electrical Engineer* of June 28th gives some particulars of a case in which a man was killed in a Fifeshire colliery through coming in contact with a wire rope which was attached to a cable connected with an electric coal-cutter. Electrical engineering experts from various parts of the country were present to give evidence. The vulcanised shield of the cable entering the motor casing had become worn through, thus allowing the live wire to come into contact with the metal of the machine casing and thereby charging the whole machinery. It was stated that an accident of the kind had never before happened in a similar way.

THE LANCET.

LONDON: SATURDAY, JULY 6, 1907.

The Imperial Cancer Research Fund: Fifth Annual Report.

FIVE years have now elapsed since the foundation of the Imperial Cancer Research Fund and though no definite information has been obtained either as to the etiology or the treatment of cancer, yet much good and useful work has been accomplished and our general knowledge of the distribution and the laws of growth of malignant disease has been advanced. In many parts of the world there is great activity in cancer research and Dr. E. F. BASHFORD, the superintendent of the Research Fund, has done well to keep himself in touch with the more important of the movements. He attended by invitation the Toronto meeting of the British Medical Association and took part in a discussion on the subject of cancer; and subsequently he visited many of the laboratories in the United States, including the Rockefeller Institute, in which cancer investigations are being carried on. Later Dr. BASHFORD was present, as the representative of the Imperial Cancer Research Fund, at the International Cancer Congress held in Heidelberg and Frankfort. Some of the German representatives of this Congress have lately proposed the establishment of a permanent international conference on cancer with its headquarters in Berlin. On the whole we are inclined to agree with Dr. BASHFORD that at present little advantage is to be gained by such a conference and that more good will be attained by encouraging active intercourse and exchange of material between investigators who are studying cancer in the laboratories of different countries. This interchange of material is of great importance and we are glad to learn that the Imperial Cancer Research Fund has provided material for investigation to numerous other workers both in this country and abroad.

Our chief hopes of the attainment of an exact knowledge of cancer depend, it is generally acknowledged, on experimental investigations. Statistics have done their share and it is probably useless to expect that very much more information of importance will be obtained from these. Statistics, however, have given us some striking facts, the true meaning of which will be known only when the problem of the etiology of malignant disease has been solved. It is certain that some allowance must be made for want of accuracy in all statistics but even when more than enough allowance has been made for this source of fallacy we find many strange facts which must be of great importance. For instance, we find that of 1589 cases of malignant disease reported from India, only in 76 cases did the growth affect internal organs, while in 1513 cases the surface of the body was the part involved. It is clear from even a moment's consideration that this fact points to a cause coming from outside and in most cases not entering the body with the food. We learn further that in 335 persons afflicted with cancer the diet was vegetarian and in 608 persons the diet was mixed but flesh for the most part. It is obvious, however, that these facts tell us little, for we are not told what was the relative proportion of vegetarians and those using a mixed diet, and therefore the figures are useless. It is of interest to note that by statistics we learn that the incidence of cancer, as recorded for different sites of the body, varies so that in some parts of the world malignant disease is especially liable to attack special regions of the body; for instance, in the native races of Africa melanotic sarcoma appears to be especially frequent and it always attacks the soles of the feet. This fact points strongly to some cause arising from the ground and attacking the bare feet of the natives. In India, as we have already stated, the surface of the body seems to be especially liable to be attacked and in Kashmir epithelioma of the anterior abdominal wall occurs with a constancy met with nowhere else. Peculiar forms of chronic local irritation met with in native races associated with native customs or religious rites are reported to affect those portions of the body which correspond to the sites on which the majority of cancers occur. These are analogous to the chimney-sweep's cancer and the paraffin and x ray cancers seen in this country. In some cases the damage to the part predisposing to the occurrence of malignant disease has been caused by a specific inflammatory condition, as may be seen in lupus and in some forms of leucoplakia of the tongue. Inasmuch as no one form of external irritant is constantly associated with the development of cancer, it is clear that the mere irritation is nothing more than a preparation for the development of malignant disease. It is evident that some intracellular change occurs which transforms a normal cell into a cancerous cell. As to what this change is we know nothing at present and in our attainment to a knowledge of that change lies our hope of a knowledge of the true etiology of malignant disease.

It will be of interest to take a brief glance at the chief experimental work on mice that has been done in the laboratories of the Imperial Cancer Research Fund. During the year 48 additional spontaneous tumours in mice have been added to those previously studied and in all 40 tumours have been successfully propagated from mouse to mouse, and among these are two fresh groups—namely, certain carcinomata of the mamma with a great tendency to hæmorrhage and certain squamous-celled carcinomata. The hæmorrhagic carcinomata are the most frequent form of cancer in the mouse and Dr. MURRAY, Dr. MAGNUS HAALAND, and Mr. W. H. BOWEN have been very successful in propagating them, though other investigators have failed. The squamous-celled carcinomata are of especial interest, for there can be no doubt that they are true carcinomata and thus the doubts which were expressed as to the carcinomatous nature of propagated tumours are completely dispelled. The results of the propagation of JENSEN'S tumours met with much opposition, as it was asserted that they were not genuine cancers. In all these transferred tumours there are seen the same alternations of periods of exacerbation and remission as occur in cancerous human beings. At times the growth is rapid and anon it seems as if all growth has ceased including the prostatic portion, is a tube having its wal's in contact and presenting on section a transverse slit, —, the prostatic portion being somewhat curved with the convexity upward, ⌒. Believing, however, that an oval instrument might well possess an advantage over a round one, provided the long diameter of the oval was transverse instead of vertical, I had catheters specially made for me in France by the courtesy of Messrs. Allen and Hanburys. On trying one of these in my case I found it was passed with perfect ease, both by myself and my patient who volunteered the opinion that he had never passed a catheter so easily and comfortably, nor did it cause bleeding. The catheter, thus modified, is of elastic gum, silk web, coudé, oval, flattened transversely, ⬭, with the beak curved on the *flat*.

It may be had in 11 sizes (12–22) from Messrs. Allen and Hanburys, Wigmore-street, W.

It was stated that an accident of the kind had never before happened in a similar way.

requiring inquests lie within different jurisdictions. The practice to be adopted on such occasions may be suggested by the law officers of the Crown advising the Home Office or by the council of the Coroners' Society but does not have its origin in any provision on the part of the legislature. The dispute arising with regard to the holding of post-mortem examinations in a coroner's district in London has been frequently referred to in these columns. It illustrates in a striking manner the looseness and insufficiency of the sections providing for medical evidence in the present Act. One of the undecided points connected with the calling of medical witnesses at inquests, to which the report under consideration gives some prominence but upon which it finds a difficulty in pronouncing an opinion with confidence, arises out of the following conditions of frequent occurrence. A medical witness is summoned by the coroner to give evidence as to the cause of a death, which does not need for its elucidation more than the external inspection of the cadaver without examination of the internal organs or of the brain. The medical man may be desired to make such an inspection by the coroner or he may do so from a conscientious desire to qualify himself fully for the giving of his evidence. Should he then be entitled to a fee of two guineas provided by the Act for a "*post-mortem* examination" or only to the guinea of the ordinary medical witness? According to the advice given by the council of the Coroners' Society an external inspection of the body is not a post-mortem examination within the meaning of the Act, even when ordered by the coroner. The report is careful to point out how doubtful the question is and to suggest the necessity for tact and discretion to avoid disputes on the subject and a possible deadlock. Looking at it from the point of view of the medical man we should be inclined to differ from the view expressed and to say that the coroner ordering an examination with a view to obtain the best evidence of the cause of death should be taken to require as thorough an inspection as the case may demand, and that the question of how complete that examination should be is one which ought to be decided according to the facts of a particular case and as to which the medical witness and the coroner should be in accord. The external examination may, when properly made, be an unpleasant or a dangerous task and the examination of internal organs may be comparatively simple and free from disagreeable or dangerous circumstances. In other words, in the case of either form of examination the medical man will have a responsible professional duty allotted to him, which may be ill-remunerated by a fee of two guineas or may not. He has to "take the rough with the smooth," and those who employ him should not grumble at being obliged to do the same. The term "post-mortem examination" has not been defined or limited by the Act and to say that it may be taken to imply *such an* examination of a dead body as may be desirable in order to place the cause of death beyond doubt involves no straining of its natural meaning. Another important question referred to the Coroners' Society by its members during the past 12 months has arisen out of the scheduling of a number of industrial diseases as accidents under the new Workmen's Compensation Act. The council of the society is of opinion that the coroner informed of a case within his jurisdiction where death is ascribed to one of these diseases will act rightly in holding an inquest.

Naturally the questions propounded for the consideration of the council of the Coroners' Society are not all of as general interest as some of those which we have mentioned, nor are they as difficult of solution. Clearly a right answer could be given without hesitation to an inquiry as to the course to be adopted when there was the evidence of a few remains of bones, buttons, and buckles, to show that someone, probably an unidentifiable tramp, had met with his death in a cement kiln, into which presumably he had crawled for warmth and shelter. There can be no doubt that, although the coroner may not have "the dead body of a person" before him in such a collection of relics, he would be extremely unwise to decline to hold an inquest. Again, to take another instance, a deceased person had evidently died through injuries sustained by violence more than a year and a day before his death and the coroner had doubts as to what he should do. The correct, and at the same time obvious, reply was to the effect that although the period which had elapsed might save the guilty person from trial on the capital charge, the duty to inquire into the cause of a death credibly stated to be unnatural and violent was not affected thereby. Many other points of varying interest and importance are touched on in the report before us but enough examples have been given to show that difficulties are likely to perplex coroners (who by the nature of their work have already enough to occupy their thoughts) and to cause friction between them and the local authorities, or the medical profession, or the public, all or most of which might justly be removed by a carefully considered and clearly drafted Act of Parliament. Such an Act might also simplify the coroner's duties in respect of such quaint survivals as inquests upon treasure trove and might introduce a uniform system of inquiry into causes of fire not resulting in death. If it is considered that investigations should be held in the case of fires occurring in the City of London it can hardly be contended that they would be undesirable elsewhere, although possibly a better manner of conducting them might be devised. The duties of coroners, however, so far as inquests upon dead bodies are concerned, are almost indissolubly connected with the whole matter of death registration and burial, so that fresh legislation with regard to the one cannot be satisfactory unless it is undertaken in conjunction with corresponding reform in respect of the other.

The Bacillus Paralyticans and General Paralysis of the Insane.

THAT the intelligent and successful treatment of any given disease is absolutely dependent upon a correct appreciation of its associated pathological processes and particularly of its ultimate etiological factor may be stated as a fundamental principle which is well illustrated by that condition known as general paralysis of the insane, for despite the many years during which the disease has been familiar to and even some of the tumour already formed disappears. All who have had much experience of carcinoma in man will agree that these variations in the growth of cancers occur quite apart from any method of treatment adopted and it is this lack of uniformity in the progress of malignant new growths that is mainly responsible for the curative reputation of many drugs. In propagated cancers in mice there is marked variation in the degree of proliferation and while in some cases the proliferation is greater than is ever seen in spontaneous cancers, in others the rate of growth hardly exceeds that of normal tissue. Attempts to cultivate tumour cells outside the body, even when the organic fluids of the mouse have been employed, have proved fruitless and it is only in the responsive living environment of the mouse's body that the vitality and peculiar energies of the tumour cells manifest themselves. The favourable conditions for growth presented by normal mice can be altered to the disadvantage of the tumour cells, so that they are unable to proliferate. The soil can be rendered unsuitable for the growth of transplanted tumour cells in many ways: as when a mouse has recovered from a previous successful inoculation of cancer tissue of its own species, or when previous inoculation has not been successful but has led to the absorption of cancerous tissue, or after the previous inoculation of the blood of a normal mouse. Some infective diseases also hinder the growth of inoculated cancer tissue. The protection produced by the spontaneous absorption of tumours, which had grown for a time, is most efficient against inoculations of tumours of the same strain as that which had been absorbed; it is less for tumours of different strains and may even be wanting. As to the mechanism of the protection we are in doubt but the fact that the protection produced by mouse cancer and mouse tissue is not produced by cancer or tissue of other species of animals shows that the cells implicated are mouse cells, having nothing in common with the cells of cancers of other animals except their mode of growth. Satisfactory evidence is still wanting of the existence in the serum of protected animals of substances directly harmful to the cancer cell. Many "cancer cures" have been tested during the past year; unfortunately it has proved impossible to attribute any curative value to even one of them, in so far at least as regards the inoculated carcinomata of mice. We are glad to see that the financial aspect of the Fund is much more satisfactory than when we reviewed the progress of its work last year. Then we had to deplore the fact that almost from its foundation the annual receipts of the Fund had not sufficed to meet the annual expenses. During the past year not only have the receipts exceeded by £1200 the receipts of the preceding year, but a munificent donation of £40,000 has been received from Mr. and Mrs. BISCHOFFSHEIM. The amount is invested and the dividends are to be applied to the general work of the research. This is not the first donation from this source, for at its beginning Mr. BISCHOFFSHEIM gave £5000 to the Fund. With such happy auguries for the financial success of the Imperial Cancer Research Fund we cannot doubt that the Fund will be able to carry on the good work of research and though it is impossible to foretell how soon the mysteries of cancer will be revealed we shall feel that all that is possible is being done to bring to light the secrets of malignancy.

The Annual Report of the Council of the Coroners' Society.

THE report of the council of the Coroners' Society for the year 1906-07 lies before us and if it contains matter primarily intended for the perusal and the guidance of the coroners for whose benefit it is issued there is little in it which might not be read with advantage by all members of the Government or of the Houses of Parliament desirous to promote useful legislation in the public interest. The work of the coroner, in deciding whether an inquest shall be held upon a body lying within his jurisdiction, and in the proper conduct of the inquest, including the obtaining of necessary evidence, is in the main regulated by a statute passed 20 years ago. Other Acts since the Coroners Act, 1887, may have increased the number of cases to be inquired into but have done so without rendering more explicit the vague definitions and scanty directions of the original Act which was based upon predecessors passed when medical science and the activity of the police were alike undeveloped, when the protection of the worker at his work had not exercised the minds of the benevolent to any considerable extent, when the importance of accurate statistics concerning the causes of mortality was not realised, and when it was only thought necessary to sketch in outline the functions of an official whose ancient powers and importance had been considerably curtailed. The coroner is not a judge whose decisions are liable to constant discussion and revision in the High Court of Justice but his position is not on that account a bed of roses. In the fulfilment of his duties he is naturally exposed to the hostility of individuals, honest and dishonest, or he may incur the disapproval of the local authority responsible financially for his disbursements. At any time his acts or omissions in the exercise of his duties may be brought to the notice of the Lord Chancellor or of the Home Secretary; and whether he has done rightly or has fallen into one of those errors to which all are liable in the exercise of a vaguely defined discretion, the affair will probably cause him considerable trouble and anxiety. For his guidance in matters upon which he is unable to obtain the direction of the Secretary of State the Coroners' Society will supply a member in doubt with a useful opinion based upon the experience of others and upon authorities which may be beyond his reach. The report to which we have referred contains many examples of opinions thus given which, as has been suggested, not only elucidate the points at issue but which also illustrate the need for a new and comprehensive Coroners Act. The unsatisfactory nature, for example, of the clause which defines the occasions on which inquests should be held is shown by many examples, including the suggestion that its strict interpretation might have led to an inquest being held upon any of the bodies brought over to England for burial after the recent terrible wreck of the *Berlin* or upon a body similarly transported home after a fatal accident in the Alps.

Again, when a single accident produces many deaths the question how many "inquests" are to be held is of importance in regard to the exact procedure to be adopted, and the results of such an accident may again be complicated for the coroners concerned if, through the occurrence taking place on the confines of one or more districts, bodies were to be vested in the President who had unlimited powers to appoint and to remove at pleasure all officers and members of the council, to vary and to rescind all regulations and by-laws, and "generally to do or direct to be done all acts and things which in his discretion he might deem conducive to promoting and effecting the objects of the Corporation." As soon as the text of this Bill came into our hands we pointed out that, while we were in absolute accord with the high respect for the throne and for the wise and enlightened monarch now ruling over us, shown throughout the Bill, we considered that this respect might have been evinced without casting upon the occupant of the throne responsibilities which in conceivable circumstances might be most heavy and irksome. We made the obvious point that our present Sovereign succeeded as a man of mature judgment, with wide and cultivated sympathies, and with a knowledge of men and things which would have won for him high distinction in whatever position fate had placed him; and we realise with alacrity that in his heir the citizens of the British Empire must feel that they possess one worthy to discharge the tremendous task that in the course of nature will devolve upon him. But we have felt ever since the Bill for the incorporation of the Fund was first made public that, although future Sovereigns might be expected to emulate the example of His Majesty the KING and of His Royal Highness the PRINCE of WALES by bringing to the conduct of public affairs the same intelligence, fairness, and assiduity, this supposition must not be treated as a certainty. We also considered that it was not fair to leave the President or the Sovereign, independent of all assistance, to exercise an unfettered judgment in matters always difficult and liable at any moment to become complicated or technical. This view was independently expressed by the British Medical Association and largely indorsed by the lay press. As might be expected, it has been met with absolute and gracious approval by the illustrious persons concerned, and valuable concessions have accordingly been made.

On the order for the consideration of the Bill Dr. V. H. RUTHERFORD, the Member for the Brentford division of Middlesex, moved the recommittal of the Bill with an instruction that clauses should be inserted providing for the constitution of a council for the Fund upon representative lines. The honourable Member suggested that the public requirements would be met if the elected members represented one from the City of London, one from the London County Council, one from the University of London, one each from the Royal Colleges, two from the British Medical Association, and one each from the Metropolitan Hospital Sunday Fund, the Hospital Saturday Fund, and the Central Hospital Council. The amendment embodied a view which we had already advocated—the view that the contribution of the medical profession to the efficiency of the hospitals and to the carrying out of their work should be reckoned side by side with, and in combination with, the support of the ever-generous public. But Dr. RUTHERFORD'S arguments did not find favour with the House nor were all those who supported him, among whom none of our medical legislators were to be found, happy in their words or able to discuss the question from any broad scientific position. The Attorney-General, in reply to Dr. RUTHERFORD'S contention, pointed out to the House the extent to which the constitution had already been altered from the point of view of safeguarding public interests, and speeches by the Prime Minister, by Mr. BALFOUR, and by Sir WILLIAM COLLINS made the withdrawal of the amendment a certainty. The Attorney-General explained that a provision had already been introduced that on the termination of the tenure of office by the present President it would be necessary for the Lord Chancellor, the Prime Minister, and the Governor of the Bank of England for the time being to concur in the recommendation of some member of the Royal Family whom they considered qualified to accept the post now occupied by the PRINCE of WALES, the member of the Royal Family being the son, grandson, or brother of the Sovereign. There is therefore assurance that three persons holding high and responsible public positions must be united in recommending a qualified President, while if they do not concur the duties of President will devolve into the hands of three persons; there would no longer be a President but three governors. Sir LAWSON WALTON went on to show that since the Bill had left committee an important clause had been added limiting the individual power of the President so that on his own part and on his own authority he could not deal with the distribution, investment, or application of the property. He would be controlled by the majority of his council in all matters relating to the investment, expenditure, application, and distribution of money. The speaker added, amidst the cheers of the House, that while the power of the President would thus be limited on his own motion to the collection of money, the name of the Royal Family would be connected with the appeal to the public for funds, and that it was this association which had created the Fund and given to it its magnificent success. He considered that in any scheme for hospital management there would inevitably be a large representation of the medical element, and, of course, at the present moment medical men of the greatest eminence are upon the Council of the Fund. He evidently saw difficulty, also, in the way of securing representation of the various London hospitals upon the body which would distribute money annually to these hospitals—a point made later by Sir WILLIAM COLLINS. Although we do not consider that this difficulty would really be very great, we realise the advantages of not fettering a young institution with too strict and complicated a constitution. It has to be remembered that what is done by statute can only be undone by statute.

The Prime Minister followed upon the same lines of general approval of the Bill as amended in committee. He pointed out the conspicuous success of the Fund, which has distributed money at the rate of £100,000 a year, with a percentage of expenses of 1·35 per cent. He emphasised the representative character of the existing Council and his belief that there would always be a desire to place upon the Council persons similarly qualified to give the best advice to the President. He added that a further concession would be made to the desire that the financial control of the Fund should be above all reproach, and he gave notice of an amendment that the accounts of the

the neurologist, has been diagnosed, and studied, its average duration remains about two years from the onset of symptoms, and of curative treatment there is none. In such circumstances Dr. W. Ford Robertson's investigations into the bacteriology of general paralysis are deserving of the warmest praise but the importance of the subject demands that his experiments and the conclusions drawn from them should be subjected to the most rigid scrutiny. We therefore note with satisfaction the representative audience which assembled at the last quarterly meeting of the Medico-Psychological Association when Dr. Ford Robertson, in conjunction with his junior colleague, Dr. G. Douglas McRae, presented a communication on Further Bacteriological and Experimental Investigations into the Pathology of General Paralysis. The substance of this paper may be briefly summarised.

A number of strains of diphtheroid bacilli, all "Neisser-positive," which had been isolated from cases of general paralysis or of tabes dorsalis, were tested as to their fermentative activities in various carbohydrate media. By means of their several reactions these bacilli were differentiated into two distinct species, named respectively bacillus paralyticans longus and bacillus paralyticans brevis, and to them severally and collectively Dr. Ford Robertson and Dr. McRae ascribed specific pathogenic properties. Each of these species was in some instances virulent for the mouse but never for the guinea-pig; while by the prolonged feeding of rats with cultivations of these bacilli symptoms and lesions similar to those of general paralysis of the insane were produced in the rodents. Discussing the question of the portal of entry Dr. Ford Robertson and Dr. McRae distinguish between general paralysis of the insane, in which the infective focus is situated in the buccal and naso-pharyngeal mucosæ, and tabes dorsalis, where the point of invasion is the whole of the genito-urinary tract and the lower part of the alimentary canal; and they affirm that in these situations they have obtained evidence of actual tissue invasion, as opposed to mere contact, by these particular bacilli. Reference was also made to the immunisation of the sheep to the bacillus paralyticans and to the associated rise in the phagocytic index of the serum observed during the process. In the discussion which followed, and in which some well-known bacteriologists as well as clinicians took part, the opinion was almost universally expressed that although the disease was in all probability primarily a toxæmia, yet the evidence adduced by Dr. Ford Robertson and his colleague was insufficient to justify the claim to specificity advanced on behalf of the bacillus paralyticans, or even to demonstrate the bacterial origin of the toxin. Indeed, one observer, Dr. George M. Robertson, who detailed some experiments supporting Dr. Ford Robertson's original statements that a diphtheroid bacillus was invariably present in general paralysis, stated that he had now observed this association in nine out of ten cases examined in the Stirling District Asylum—the organism being isolated from the peripheral blood in no less than seven cases—but that in no case was the organism isolated identical with bacillus paralyticans. Then, too, those criteria of specificity advocated by our own countryman, Henle, but more generally referred to as the "postulates of Koch" were freely invoked by many of the speakers, and the observations of Eyre and Flashman recorded a few years back, which showed that the presence of diphtheroid bacilli in the buccal and naso-pharyngeal mucosæ was not peculiar to the general paralytic but could be observed in similar situations in patients suffering from other nervous lesions and in the sane, were referred to; and it was pointed out that diphtheroid bacilli were fairly common saprophytes; were found in some articles of food, e.g., milk, and in numerous situations on and in the body, in health as well as in disease, particularly in the genito-urinary tract; and were frequently encountered in morbid material side by side with micro-organisms which were of themselves capable of producing the special lesions with which they were associated.

This ubiquity of diphtheroid bacilli, many of which are indistinguishable from the organisms isolated by Dr. Ford Robertson, actively militates against their suggested possession of pathogenetic properties, and in this connexion it may be remarked that even tissue invasion by purely saprophytic bacteria is not unknown and we might instance the condition known as xerosis conjunctivæ where diphtheroid bacilli undoubtedly invade the membrane and may be demonstrated in sections throughout the entire thickness of the altered conjunctiva, but in spite of this fact it is now generally conceded that the xerosis bacillus plays no part in the causation of the affection. Again, it is assumed by Dr. Ford Robertson that the elaboration of bacteriolytic substances in response to the introduction of cultivations of bacillus paralyticans into the animal body necessarily denotes the possession of pathogenetic properties by that bacillus, regardless of the fact that inoculation with practically any and every bacterium, virulent or harmless, will stimulate the formation of special antibodies. Enough has been said to indicate the present open-minded attitude of the profession towards these researches and we have no doubt that Dr. Ford Robertson will be stimulated thereby to further investigations directed possibly in the first instance towards the removal of the objections now urged.

◆

King Edward's Hospital Fund for London.

The Bill for the incorporation of King Edward's Hospital Fund for London was ordered for third reading on Monday last, July 1st, in the House of Commons, after a debate of the greatest interest to the public at large as well as to all hospital authorities and to the medical profession. The debate turned largely upon the proper constitution of the Council of the Fund. It will be remembered that the original Bill provided that His Royal Highness the Prince of Wales should continue the position of President of the Fund in the position of President of the corporation during the pleasure of the Sovereign, and that every succeeding President should be appointed and hold office during the pleasure of the Sovereign, the whole management of the corporation thus remaining with the President, or through him with the Sovereign. The direction, control, and management of the affairs of the corporation and the application of all moneys, property, and income calculated to induce a man to *scamp* his work. It would be hard to conceive a more unfounded accusation or a more unjust proposal. We greatly regret to record that the council adopted the principle put forward by its works and highways committee that it shall appoint such a number of practitioners as may be necessary for the purposes of this very shabby piece of contract practice. We trust it will find more difficulty in filling the posts than it appears to anticipate.

THE BIRTHDAY HONOURS.

OF the 14 medical men who have been the recipients of honours on the occasion of the King's Birthday ten are members of either the naval or military medical services, while four belong to the civil branch of the profession. Of these latter, one is a Governor and Commander-in-chief of a British colony. Two knighthoods have been conferred on medical men—namely, Mr. Henry Rosborough Swanzy, F.R.C.S. Irel., and Mr. Thomas Boor Crosby, M.D. St. And., F.R.C.S. Eng. Sir Henry Swanzy is President of the Royal College of Surgeons in Ireland and late president of the Ophthalmological Society of the United Kingdom. He is surgeon to the Royal Victoria Eye and Ear Hospital, Dublin, and ophthalmic surgeon to the Adelaide Hospital, Dublin. Sir H. Swanzy's contributions to the literature of ophthalmology are many and do not call for any detailed notice on our part, for the value of his ophthalmological work is well recognised. Alderman Sir Thomas Crosby is a sheriff and justice of the peace for the City of London. The names of eight medical men appear in connexion with the most honourable Order of the Bath. Inspector-General Herbert Mackay Ellis, K.H.P., director-general of the medical department of the Royal Navy, receives a Knight Commandership of the Order, whilst Colonel Charles Henry Beatson, I.M.S., Colonel George Deane Bourke, R.A.M.C.; Deputy Inspector-General Thomas Desmond Gimlette, R.N., Surgeon-General Francis Wollaston Trevor, A.M.S., Surgeon-General Thomas Tarrant, K.H.P., A.M.S., retired; Deputy Surgeon-General Edward Malcolm Sinclair, late A.M.S., retired; and Deputy Surgeon General Alfred Eteson, I.M.S., retired, are made Companions of the Order, the three last named receiving the honour in connexion with the fiftieth anniversary of the Indian Mutiny. Sir William MacGregor, K.C.M.G., C.B., Governor and Commander-in-Chief of Newfoundland, who is an M.D. of Aberdeen, has been promoted to a Grand Commandership of the Order of St. Michael and St. George. At one time he held resident appointments at the Glasgow Royal Infirmary and at the Royal Lunatic Asylum, Aberdeen. He was also assistant government medical officer in the Seychelles. He has been chief medical officer in Fiji, receiver-general and administrator of the Government, and Acting High Commissioner and Consul-General for the Western Pacific, administrator of British New Guinea and Governor of Lagos. On Dr. Jean Etienne Justin Schneider, principal medical officer of the first class in the French army and late chief medical officer to the Shah of Persia and president of the Sanitary Council of Persia, has been conferred an Honorary Companionship of the Indian Empire. Surgeon-Lieutenant-Colonel Warren Roland Crooke-Lawless of the Coldstream Guards, surgeon to His Excellency the Viceroy of India, becomes a Companion of the Indian Empire. The Kaisar-I-Hind *medal* has been conferred upon Rai Bahadur Asutosh Mitra, L.R.C.P., L.R.C.S. Edin., the chief medical officer in Kashmir. Professor Edwin Ray Lankester, F.R.S., who has been made a Knight Commander of the Bath, though not a member of the medical profession, deserves special mention in connexion with the birthday honours. As Fullerian professor of physiology and comparative anatomy in the Royal Institution of London and as Linacre professor of comparative anatomy at Oxford he has done most excellent work, while his position as director of the Natural History Department of the British Museum has brought about a beneficent revolution in the study of natural history. The name of the Lord Mayor of London, the Right Hon. Sir William Purdie Treloar, who has been made a baronet, also must not be omitted. As president of the Metropolitan Hospital Sunday Fund and by his untiring efforts to ameliorate the sad lot of crippled children he has done good work. To all these recipients of well-earned honours we offer, on behalf of the profession, hearty congratulations. Since the issue of the Birthday Honours list the *London Gazette* of July 2nd contains the announcement that the King has appointed Sir Joseph Dalton Hooker, M.D. Glasg., G.C.S.I., C.B., F.R.S., to the Order of Merit. Sir Joseph Hooker, who is a late director of the Royal Gardens at Kew, is a retired surgeon of the Royal Navy and was surgeon and naturalist to the Antarctic Expedition of 1839–43 in the *Erebus* under Sir James Ross. From 1872 to 1877 he was president of the Royal Society. Our congratulations to this distinguished botanist and member of the medical profession upon his appointment will be shared in by members of the medical and scientific professions all over the world.

THE REPORT OF THE EGYPTIAN GOVERNMENT HOSPITAL FOR THE INSANE FOR 1906.

WE see by the report of Dr. J. Warnock, the director, that the average number of patients during the year was 695 and that by the evacuation of certain buildings used until now by the Egyptian Army hospital the asylum will shortly consist of 812 beds. Moreover, a new asylum is to be opened in three years' time to provide for the great number of chronic insane cases which still have to be discharged to make room for acute patients. These figures are very different to the 300 beds which for many years were considered enough for the insane men and women of the whole of Egypt. Among the improvements are chronicled the addition of a female charge nurse, a qualified dispenser, and several attendants and servants, and, most important of all, the railing in of a hundred acres of desert land surrounding the asylum, which will provide sufficient airing courts. Several improvements have again been postponed for want of funds, such as the building of workshops for male patients and residences for several of the junior employees, including the night attendants. The net daily cost per patient is a trifle over 1*s.* 4*d.* Attention has been drawn by the Government to the necessity of removing dangerous weapons from the insane before conveying them to Cairo from the country districts and also to the desirability of providing those patients with clothes who are destitute of any covering. The former injunction is quite necessary when we read that out of 67 men and women admitted during the year, charged with various offences, no less than ten were accused of murder and eight with attempted murder. The whole number of admissions was 563, and among these were 12 suffering from fractured ribs, arms, leg, and jaw. The popular belief in oriental countries that imbeciles and weak-minded youths are harmless and do not require asylum care is entirely contradicted by experience in Cairo, and Dr. Warnock again draws attention to the reprehensible habit among children of teasing these unfortunates and thus provoking criminal retaliation. This class of cases requires asylum interference to save them from ill-treatment and to prevent their retaliating on their tormentors. More than half the patients admitted were suffering from pellagrous insanity, mania, or hasheesh insanity. 33 patients, mostly Egyptians, were admitted suffering from general paralysis, and all of them except one man and one woman (a *prostitute*) had either the signs or history of previous syphilitic infection, Fund should be annually audited by an auditor nominated by the President of the Local Government Board, the Board to fix his remuneration. Mr. BALFOUR hoped that the speech of the Prime Minister would enable the House to come to a unanimous vote and alluded to the fact that Dr. RUTHERFORD'S amendment asking for a small representation of the medical profession had received its chief support from a Member of the House who evinced distrust of that profession. This was unfortunately the case and, taken with the absence of backing from the medical members of the House, doomed Dr. RUTHERFORD'S amendment to failure. The wish of the House was unmistakeable that, at present at any rate, the medical profession should not have statutory powers of representation upon the Council. In the circumstances we would ask the medical profession to believe that the Council of King Edward's Hospital Fund for London will discharge its duties in advising the Sovereign or the President, in the future as in the past, with every regard for our profession. By its increased powers this Council has become a public guarantee of the sound financial control of the Fund, and the representation of the medical profession which now exists in its body may be reasonably expected to continue.

Annotations.

"Ne quid nimis."

PRESENTATION OF THE FREEDOM OF THE CITY OF LONDON TO LORD LISTER.

ON June 28th the City of London honoured Lord Lister and her own freemen by entering upon the roll of that distinguished company the name of Lord Lister. It was a matter of congratulation that the council was able to make such arrangements as enabled the illustrious surgeon, though in a weak state of health, to attend in order to be presented personally with the freedom. He was welcomed by a distinguished gathering which included many well-known names in medicine and surgery and representatives of all the chief official bodies of the profession. The freedom was presented in a golden casket of extreme beauty, the official words with which the honour was conferred being: "In recognition of his eminence as a surgeon, and of the invaluable services rendered to humanity by his discovery of the antiseptic system of treatment in surgery, whereby so great a progress in medical science has been achieved, so much suffering has been alleviated, and so many valuable lives have been prolonged." The whole proceedings were marked with the greatest enthusiasm and the honour done to our famous leader must be felt by all members of the medical profession as one done to ourselves, our calling, and our aspirations. This note was struck in the opening sentence employed by the City Chamberlain, Sir Joseph Dimsdale, in the address admitting Lord Lister to the freedom, when he recalled the fact that in 1803 the same honour was paid to Dr. Edward Jenner, "whose name would ever be associated with the discovery of vaccination and whose researches superseded the system of inoculation successfully employed a century ago by Dr. Fothergill and Dr. Dimsdale" (the latter, we believe, being the speaker's eminent relative). Sir Joseph Dimsdale proceeded to deliver an eloquent summary of the blessings to mankind that had followed upon the new era of surgery heralded by Lord Lister's discoveries and their practical application. To medical men this is an old story, but, like some of the beautiful stories of our Scriptures, we do not weary of the repetition. It gives us a sense of the grandeur of our avocation to feel that one of us, by the application of genius and prescience, by untiring industry, and by the bravest powers of self-criticism, should have been able to alter, and to alter radically, the existing relation of man to suffering and of life to death over the whole world. Never has the freedom of the City of London been more rightly bestowed, never has the foremost civic power in the world more honoured itself in honouring a new adherent.

THE WORKMEN'S COMPENSATION ACT: MEDICAL MEN AND THE BOROUGH COUNCIL OF WESTMINSTER.

WE have before us a report made to the borough council of Westminster by a joint sub-committee of its works and highways committee dealing with the best method of meeting the council's responsibility for its injured and sick workmen with special reference to the Workmen's Compensation Act. Whilst sympathising with any municipal effort to keep down the expenditure of the ratepayers' money, we cannot congratulate the borough council of Westminster on the means it has in this instance recommended, for we hardly remember to have seen a more shameless and unblushing instance of the time-honoured and simple money-saving principle of "Exploit the Doctor." It appears that Councillor J. P. Wallis has been at pains to discover the average sum paid by friendly societies to their medical officers, and this for attendance, medicine, and medical certificates he puts down as 4*s*. per man per annum. He suggests that this would be an adequate basis of payment to make for the council's workmen who live within a three miles' radius of the city hall, whilst a further 2*s*. should secure these benefits for those living beyond that radius. It is reckoned that 750 men would come under the former class and 250 under the latter, making a total annual expenditure of £225. We now quote verbatim the next section of the report which deals with the present arrangement.

> By the council's present system a workman in case of illness or accident is required to obtain weekly medical certificates from a district medical officer appointed by the council before being paid sick or accident pay. The cost of these certificates (2*s* 6*d*. each) is borne by the council, but the workmen themselves defray the expense of any necessary medical treatment, medicine, &c. The cost to the council for medical certificates supplied to workmen during the year ended the 31st March, 1906, was £303 17*s* 6*d*., and during the year ended the 31st March, 1907, it was £220 7*s* 6*d*. To this must be added the cost of printing, postage, and the time of the staff taken up in dealing with the certificates.

We are informed that the average number of sick men per week is 50 and on the new scale it is proposed to pay 86*s*. 6*d*. a week for the medical care of these men. It appears, moreover, that hitherto the council has paid an honest fee for the certification of its sick workmen but that it has so fallen from grace that now it is proposed to obtain certificates, medicine, and treatment for a less sum per annum than it has hitherto paid for the certificates alone. The justification for this proposal is an aspersion on the *bona fides* of the medical officers who have served it under the old scheme. The report states that "the duty of the medical man being confined to the issuing of weekly certificates at 2*s*. 6*d*. each"—nothing is said about the preliminary examination—"there is no inducement to pronounce a man fit for work at the earliest opportunity, as there would be were the medical man also answerable for the treatment of the patient, and were the remuneration an inclusive fee per annum. In the case of the men, whilst we are not aware that malingering has been practised to any extent, it is rendered easy, if not encouraged, by the present system." In plain English, at present the medical men will certify a workman as unfit to work for longer than is proper in order to pile up fees, whilst the new system is double-needled silk sutures, which included only the adventitia and media of the proximal end but passed through the entire thickness of the distal end. He tried the method on the carotids of three dogs, four calves, four sheep, and once on the femoral artery and abdominal aorta of dogs. Only three cases were successful; thrombosis occurred in the others. Circular suture of veins has been performed less frequently. In 1903 Jensen performed experimental simple circular suture of completely divided veins seven times, and in four the vein remained patent. In man a few cases of circular suture of vessels have been recorded. In 1896 Murphy resected and invaginated the wounded femoral artery of a young man who was shot in Scarpa's triangle. Pulsation immediately reappeared below the invagination and good recovery followed. Dr. Watts has successfully performed experimental circular suture of the arteries and veins of animals many times. He finds that completely divided vessels can be sutured with almost uniform success if asepsis is secured.

PUBLIC ANALYSTS AND STATE MEDICINE.

PUBLIC analysts throughout the country are rapidly being expected to make the diagnosis of disease by bacteriological methods part of their routine work. Hitherto the professional chemist had confined his study of bacteriology in its practical application to the examination of foods, water, sewage effluents, and to certain industrial processes in which the operations of micro-organisms are concerned and it was but a step further to add to his inquiries the diagnosis of diphtheria, tuberculosis, typhoid fever, anthrax, and so forth. Some municipal and county authorities see no objection to combining in one person, no doubt on the score of economy, the duties of both analyst and bacteriologist, and such appointments have been made by certain authorities and have been approved by the Local Government Board. It can hardly be supposed that such an arrangement is likely to interfere with the public interest assuming that the person appointed is competent both as an analyst and as a bacteriologist. It may be pointed out also that the person so appointed acts conjointly with the medical officer of health. The analyst who is also a bacteriologist, in fact, relieves the medical officer of health of a considerable amount of work, a relief which enables the latter to devote more time to his duties as an administrator of sanitary affairs. The carrying out of bacteriological examination with the view of diagnosing disease is, strictly speaking, no part of the public analyst's duties and must therefore be regarded as an entirely separate office and as such should be remunerated on a separate basis and on a scale commensurate with that adopted in the case of the examination of foods and drugs. It is easy enough to decide what constitutes a bacteriological examination made purely in the interests of medicine on the one hand and one which on the other is directed to settling sanitary questions connected with food, water-supply, and the disposal of sewage. In the former case the analyst supplies material which are helpful in the diagnosis of disease and the results are of value to the medical officer; in the latter he discloses the efficiency or deficiency of preventive measures. It is a sign of the times, we suppose, that this State medicine work threatens to exceed the work connected with the examination of foods and drugs. In the report, for example, of the public analyst and bacteriologist of the city and county of Bristol for the year ended Dec. 31st, 1906, we note that while 607 samples of foods and drugs were submitted for analysis during the year the work of the laboratory included nearly 3000 examinations of pathological or suspected pathological specimens, 2549 coming under the head of diphtheria, 256 under tuberculosis, 137 under enteric fever, and ten under miscellaneous examinations, including one for anthrax. This clearly means the addition of considerable work and of an enormous responsibility to the duties of the public analyst, and this increased responsibility obviously must raise his value as a public servant which should be recognised in the shape of adequate remuneration. As it is, the view of many authorities seems to be that bacteriological work, which includes pathological inquiry, can be "thrown in" as part and parcel of the public analyst's duties and can be included for the same remuneration that a public analyst receives when his work relates only to the examination of food and drugs. We hold no special brief for the public analyst, who is rarely a medical man, but are constrained to remark that this seems hardly fair.

THE OXFORD PAGEANT.

THE University of Oxford has been accused of flouting the medical sciences but the Oxford pageant has none the less proved of subtly flattering interest to the world of medicine. The proceeds of the performances, which must amount to a large sum in view of the many thousands of spectators who attended them, are, we understand, to be devoted to the benefit of the Radcliffe Infirmary, and though the famous benefactor, Dr. Radcliffe, has not himself been represented in this great scenic triumph of university and civic history, yet medicine, as one of the members of the mediæval "Trivium," has figured there a stately genius who, caduceus in hand, played in the "Masque of Mediæval Learning," that fascinating interlude dividing into two parts the long and gorgeous series of 15 scenes which make up the pageant.

"Medicine, next divinity,"

says the quaint Prælector to the vain and serious students to whom he introduces the several characters of the masque—

"Doth teach the cure of the body,
And maketh Melancholy be
Health's ward in cheerful chancery."

Nor does medicine appear in allegory only. The chief poet of the pageant is a medical man and well-known writer of classic English verse, Dr. Robert Bridges, whose noble ode, "An Invitation to the Pageant," and not less noble prophecy of the future of Oxford, put into the mouth of Theobald of Etampes, the twelfth century pioneer in the university of the learning of the schoolmen, are not only a worthy continuation of the poetic Oxford tradition, but are in themselves fine additions to English literature. Through Theobald's prophecy Dr. Bridges now ranks with Matthew Arnold, whose phrase "the city of the dreaming towers" has become historic. Though THE LANCET is a prose journal, we may for once quote these fine lines by a "doctor." Theobald of Etampes has looked down in a dream upon—

"a lovely city in a wide vale.
High in the south the sun
Smote on her crowded pinnacles, that rose
With spiry delicacy of silver-grey,
As 'twere a fretted casket of man's thought,
Severe mid the soft wilderness of green.
Beneath her walls a river flowed meandering
Thro' flowery meads, rushes, and willowbanks,
Where the sweet birds of the stream warbled all day.
But evermore my wandering eye return'd
Unto the lovely city."

RUPTURE OF THE MESENTERY DUE TO A FALL.

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of June 23rd Dr. A. Laubie has reported a curious result of a fall from a height—fatal rupture of the mesentery without other abdominal lesion. A man fell from a height of 15 metres and died after two and a half hours. Six days later and four days after he had been interred Dr. Laubie was requested to make a necropsy. The body was that of a strong healthy man and showed signs of incipient decomposition. In the left parietal region was a contused wound measuring from 10 to 12 millimetres which did not extend to while 23 of them had, in addition, histories of alcoholic excess. General paralysis was responsible for 7 per cent. of the male patients admitted and for more than one quarter of the deaths. The death-rate calculated on the average number of patients in the asylum was 6 per cent. Among the causes chiefly contributing to the insanity of the admissions of the year pellagra comes first on the list, followed, after a long interval, by hasheesh (cannabis indica), and then, after another interval, by syphilis and alcohol. Narcotics were administered often at night to procure sleep, paraldehyde being the drug most frequently used; only seven patients were mechanically restrained during the year for short periods in order to prevent their removing surgical apparatus from injured parts, or to prevent their persistent attempts at self mutilation. The facts that 302 of the cases admitted were certified to be dangerous to others and that 155 had attempted or threatened to commit suicide show the violent nature of the patients sent to this asylum.

SOME CONSOLATIONS OF A COLD SUMMER.

WE may extract after all some consolations from the cold summer which appears to be determined to remain a predominating feature of this year's meteorology. The existence of seasonal disease is, of course, well recognised and the history of vast human scourges teaches that the greatest development of diseases, such as plague and cholera, invariably occurred during the hot season. When all is said and done the cold of summer is never so bitter or so intense as is that of the winter, and the prevalence of diseases of the respiratory organs in an indifferent summer hardly counts when compared with the swollen returns of real wintry weather. Though there may be a few isolated cases of influenza in the cold summer the disease never reaches, as a rule, the scale of an epidemic as it does in the winter. The regular appearance of certain diseases with the seasons would appear to indicate that the vital activity of the body varies at different times of the year. When for some reason the vitality of the body is lowered the liability to disease is correspondingly increased. It may not be a hard-and-fast rule, but statistics certainly show a healthier condition of vitality of the human body in spring weather than in summer weather, while in the winter the vitality is neither maximum nor minimum. The causes underlying these seasonal variations in regard to bodily vigour may not be completely understood but many suggestions on these points have a scientific foundation. It must, at all events, be clear that there are agencies coexistent with the seasons which, according to the season, either sustain or lower the bodily energies. Amongst these agencies may be counted physical, chemical, and biological phenomena. The activity and growth of certain pathogenic organisms are stimulated under the conditions of a normal summer but checked under the conditions of a normal winter. In the spring, when the resistant powers of the body appear to be at their best, it is significant that the sun's rays approach the maximum in regard to actinic or chemical power, and actinic power signifies an energising quality. Later the actinic powers diminish and give way to an increased intensity of heat rays as exemplified in the sunlight of normal summer. In some ways the weather so far has borne more the character of spring than of summer and accordingly it is possible that certain pathogenic organisms may have lost their chance of prevailing over the human body. On the score of health there would thus seem to be no objection to such a condition of things provided that the weather is not excessively wet, that the temperature is not extremely variable, and that the sun shines. The continual absence of sun, perhaps, has been the worst feature of the present summer. Still, there are compensations; there have been no deaths from excessive heat, no sunstroke, no development of those diseases which are well known to flourish in hot weather, while the toilers in the town and the country have been spared the excuse that the prevalence of hot, sunny, and perhaps stifling days has put a premium on their inclination to work. These observations may afford some consolation, but should the weather in the meantime change and render them inopportune but few of us would express regret.

THE SUTURE OF BLOOD-VESSELS.

ONLY in comparatively recent years have wounds of the large blood-vessels been treated by conservative methods to any extent. The *Johns Hopkins Hospital Bulletin* for May contains an exhaustive historical and experimental study of the subject by Dr. S. W. Watts. About the beginning of the nineteenth century lateral ligature of wounds of veins which did not interrupt the continuity of the vessel began to be adopted. But lateral ligature can be used in only a limited number of cases. If the wound is large the ligature will produce considerable narrowing of the vessel and there is also danger of slipping. Venous suture was first successfully performed in 1882 by Schede and has now come into general use. Curiously the conservative treatment of arterial wounds antedates by more than a century that of venous wounds. In 1759 Hallowell, an English surgeon, successfully closed a wound in the brachial artery by passing a pin through its edges and a thread around this. In 1889 Jassinowsky showed that arterial wounds in animals could be sutured with preservation of the lumen of the vessel. From his experiments he concluded that all recent, clean, longitudinal, oblique, or flap wounds of large vessels and transverse wounds not exceeding half the circumference should be sutured. In man arterial suture has now been performed in a number of cases. In 1902 Schmitz collected 21 cases of lateral suture of arteries, which may be classified as follows: axillary artery, seven; femoral artery, five; popliteal and brachial arteries, of each, three; and common iliac, common carotid, and internal carotid, of each, one. Experiments on animals and clinical experience show that for successful suture, perfect asepsis, a clean-cut wound which can be approximated without much tension, and careful manipulation of the vessel without much stripping of its sheath are necessary. Silk appears to be the best material. The needle should be as fine as possible; whether straight or curved depends on the location of the vessel. Continuous suture seems to be preferable to interrupted, as it is simpler and can be applied more rapidly. There is a difference of opinion as to whether sutures should penetrate the intima or not. In suturing veins it is almost impossible to avoid such penetration. By including all the coats of the vessel suture is not only simplified but made more secure. Various methods have been used for producing temporary hæmostasis—pressure with the fingers, various clamps, strips of gauze, and so on. Whatever method is used the main point is to injure the vessel as little as possible. Pressure with the fingers is the gentlest method and should be used when possible. If any leakage occurs at the site of suture slight compression will generally cause it to cease in a few minutes. As lateral suture has not been successful in large transverse wounds of vessels and in cases in which the edges of the wound were crushed or otherwise injured, attempts have been made to unite the ends of the vessel after resection by simple circular suture, by protheses of various kinds, and by invaginating one end into the other. The same methods have been used in complete transverse wounds of vessels. Circular suture of arteries of animals has not given good results; thrombosis usually occurs. Murphy of Chicago invaginated the proximal into the distal end by means of three or four performed in order to permit of thorough lavage of the bowel, a tube being worn for the purpose for some months. In both distinct improvement had resulted but the operation was yet too recent to enable the final result to be judged. He anticipated, however, that ileo-sigmoidostomy would prove to be the more satisfactory procedure and he would never hesitate to recommend it in cases which had resisted all other attempts at treatment.

THE ROYAL ANTHROPOLOGICAL INSTITUTE.

BY command of His Majesty the King the Anthropological Institute is henceforth to be distinguished by the designation of "Royal." In congratulating the institution upon its new honour we will take the opportunity to point out how well it is deserving of such official recognition. There are few sciences that have a wider range of study and certainly none that has a more direct human interest than that of anthropology. It legitimately concerns itself with such varied interests as deal with the subject of physical racial deterioration at home and that of the better appreciation of the customs and modes of thought of the native races inhabiting the many colonies and dependencies for the proper administration of which our country has made herself responsible. Anthropology is indeed no purely academic science, although happily our old universities have afforded excellent opportunities for its study, but one which actively concerns our legislators at home, our administrators abroad, and the medical profession everywhere. It is a science indeed in which the medical man who takes a broad outlook upon his profession will find an engrossing interest, and it is sufficiently wide in its application to enlist the coöperation of minds of a widely varying bent: anatomy, sociology, ethnology, genetical research, are only a few of its important branches. We trust that the new and honourable title with which its British representative has been endowed will give the science that place in the estimation of the thinking public which its great practical importance deserves.

SHELTER FOR HOMELESS WOMEN.

ANYONE who has investigated the existing provision for sheltering the homeless outcast must have been struck with the lack of any suitable accommodation for otherwise respectable women and girls who, by untoward circumstances, have drifted into the lower strata of society. In concluding the report of our Special Sanitary Commission on the Rowton House at King's Cross we said: "We would earnestly ask him (Lord Rowton) whether some similar provision could not be made for the corresponding class of females. We appreciate the difficulties, but the need is urgent."[1] Indeed, Lord Rowton, who, in conjunction with Sir Richard Farrant, was the originator of Rowton Houses, in the course of a conversation with our Commissioner admitted the necessity of cheap shelters for females, but saw so many possible difficulties in the way that he did not think it advisable to risk the erection of houses for women. We welcome therefore the scheme which Mrs. Mackirdy (Olive Malvery), the authoress of the "Soul Market," has suggested for the shelter of about 200 women and girls. Briefly, it is proposed to place in the vicinity of Westminster or Vauxhall a shelter where women can obtain a bed for 2*d*. There will be wash-houses attached to the building and a cheap food bar, a feature of which will be the provision of pure milk for babies. When once equipped and placed upon a working basis the shelter will be handed over to Mrs. Bramwell Booth, so that the public will have no further call upon their purses in connexion with the shelter. If the scheme should do no more than prevent 200 women and girls from wandering in the streets at night rather than seek the refuge of the "Doss" or "Kip" house, a great work will have been done. But we hope that the scheme will be still more successful and that eventually other houses will be built and that the blot on our city of allowing homeless but otherwise respectable females to wander at night in the streets will be wiped out. The committee for carrying out the scheme includes, amongst others, the Duchess of St. Albans, Lady Wemyss, Lady Brassey, Lord Brassey, Lord Reay, Lord Curzon, Lord Strathcona, Sir Dyce Duckworth, and Dr. T. N. Kelynack. Lady Brassey, whose address is 24, Park-lane, London, W., will gladly give further particulars of the scheme to inquirers.

EPIDEMIC CEREBRO-SPINAL FEVER.

Dr. R. M. Buchanan, bacteriologist to the corporation of Glasgow, has stated in a recent report that the meningococcus was found in nearly 25 per cent. of the individuals examined, they being most commonly adults. It was found in four convalescents on the seventeenth, thirty-fifth, fifty-sixth, and seventy-fifth days from the beginning of their respective illnesses. On various persons who had recovered from the disease being examined three of them still showed the presence of the meningococcus in the throat. One had the illness two years, one other 12 months, and a third three months ago. The results would seem to show that the infection of cerebro-spinal fever may be spread by individuals who offer no evidence of its presence. The germ may also apperently remain a long time in the throat of individuals stricken with the disease, even after recovering from it. In Scotland during the week ended June 29th there were 16 deaths from this cause registered in Glasgow, 3 in Edinburgh, and 1 in Dundee. In Glasgow the weekly report issued on June 28th showed that there were at that time 80 cases under treatment. In Belfast during the week ended June 29th there were 6 deaths registered as being due to this cause.

THE RETIREMENT OF POSTAL MEDICAL OFFICERS UNDER AN AGE-LIMIT.

SOME ten months ago the Postmaster-General issued an entirely new regulation intimating that he had decided to review annually the efficiency of postal medical officers who were over 60 years of age, retaining those only who were found to be "thoroughly efficient" and retaining none in any circumstances after 70 years of age. Since its promulgation the Association of British Postal Medical Officers has been unceasing in its efforts to obtain either great modifications in, or rescission of, this regulation. The postal medical officers contended that much hardship was involved in making so totally unexpected a regulation retrospective and that the method of determining the question of efficiency was not satisfactory because it was based on secret reports to which the medical officers had no access and to which they had no opportunity of replying; and they claimed that it was but just that a medical consultative board should be instituted before which postal medical officers would have the right to appear and to be heard in refutation or extenuation of any charge of inefficiency. It was also most strongly urged that postal medical officers would be the only servants of the Post Office liable to dismissal for inefficiency without warning of any kind being given, and likewise that they would be the only public servants to be retired from public appointments under an age-limit without any compensation or gratuity. As the result of applications made to the Postmaster-General by the Association of British Postal Medical Officers Mr. Buxton consented to receive a deputation of its members. Accordingly a deputation, consisting of Dr. E. L. Adeney (Tunbridge Wells), the president, Dr. George A. Mason (London), the

---

[1] THE LANCET, March 28th, 1896, p. 867.

the cranium. There were no signs of fracture of the skull or of injury to the brain. The spinal cord was exposed and a small extra-dural clot was found at the level of the third and fourth cervical vertebræ. The cord here felt soft but section revealed nothing abnormal. The lower part of the mesentery of the small intestine showed a blackish tint and a tear the dimensions of which were difficult to ascertain as the least traction lacerated the tissues. In the right renal region were clots of the volume of two fists and the tissues of the posterior surface of the abdomen were impregnated with blood. Dr. Laubie thought that the spinal lesions were of little importance, as there was no solution of continuity of the cord. The lesion of the mesentery he thought was the cause of death, though the intestine was intact. An internal hæmorrhage in the course of severe injury might be fatal. The effects of the former, always a grave condition, would be added to the shock of the injury. Possibly spinal concussion was also a factor in producing death.

AN ACT TO PREVENT PROCREATION OF UNFIT PERSONS.

THE State of Indiana has just passed the following drastic measure to prevent procreation among confirmed criminals and mental degenerates of different sorts:—

Preamble.—Whereas heredity plays a most important part in the transmission of crime, idiocy, and imbecility;

Penal Institutions—Surgical Operations.—Therefore, be it enacted by the General Assembly of the State of Indiana, that on and after the passage of this Act it shall be compulsory for each and every institution in the State, entrusted with the care of confirmed criminals, idiots, rapists, and imbeciles, to appoint upon its staff, in addition to the regular institutional physician, two (2) skilled surgeons of recognised ability, whose duty it shall be, in conjunction with the chief physician of the institution, to examine the mental and physical condition of such inmates as are recommended by the institutional physician and board of managers. If, in the judgment of this committee of experts and the board of managers, procreation is inadvisable and there is no probability of improvement of the mental condition of the inmate, it shall be lawful for the surgeons to perform such operation for the prevention of procreation as shall be decided safest and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable: *Provided*, that in no case shall the consultation fee be more than three ($3.00) dollars to each expert, to be paid out of the funds appropriated for the maintenance of such institution.

It would seem difficult to comprehend the exact value of this piece of legislation, for apart from the criminal it is merely directed against the "unimprovable" cases detained in the State institutions. Now in the vast majority of instances the "unimprovable" patient remains the rest of his life in the asylum and it cannot be necessary to subject him to this somewhat severe operation, when all opportunities of procreation have been, or should have been, withdrawn. It is an Act which will not assist the early placing of patients under care, as it will add another, and in this instance a very real, horror to the asylum. The perplexing patients to deal with are those who have recurrent attacks of insanity and who frequently propagate their species between these attacks. Now these persons are apparently immune from this Act. One of the great difficulties in carrying out this law will be that of deciding who are the "unimprovable" cases. There is no time limit; therefore a patient may be emasculated in the first month of his residence in the institution, provided that the board and the experts agree that he belongs to the "unimprovable" class. There is no appeal, neither does it appear that the relatives can intervene. Even were it possible to grant that this treatment is advisable and proper, surely this is a great power to place in the hands of that class of expert who would be willing to be consulted at $3 per case. Further, it must be borne in mind that many persons, especially females, rapidly degenerate mentally after their reproductive organs have been removed. Therefore in eliminating the bare chance of a given patient begetting an insane offspring it will be within the bounds of possibility that she may be made chronically insane, whereas if not operated upon she might have recovered. We are not certain that it has been proved that a large proportion of the insane are the offspring of "confirmed criminals, idiots, rapists, or imbeciles"; therefore this scheme of legislation would appear to be more vexatious than practical. We do not say much regarding the confirmed criminal, for presumably he is in possession of his faculties, and if the risk of emasculation is added to the detention in gaol the enhanced penalty may deter the thief or the wife-beater from his evil practices. In conclusion, we feel bound to condemn this enactment, for the objections are great compared to the small good which may be gained; for, whilst fully appreciating the importance of doing something to prevent the spread of insanity, we should prefer to rely on less drastic legislation, together with the education of the public, rather than in seeking the remedy by the surgical knife.

OPERATIVE TREATMENT OF THE LARGE BOWEL.

Dr. Robert Hutchison, in the course of some recent remarks in the wards of the London Hospital on the treatment of muco-membranous colitis, after discussing the treatment by diet, considered the question of ileo-sigmoidostomy with the removal of the colon. In regard to diet there were, Dr. Hutchison said, two diametrically opposed schools of teaching. Most German authorities, headed by von Noorden, appeared to recommend a bulky diet rich in cellulose, such as was commonly prescribed in the treatment of ordinary constipation. French authorities, on the other hand, whose experience of the disease at Plombières was peculiarly large, employed a diet which was calculated to leave as little residue in the bowel as possible. Personally, he agreed entirely with the French plan and commonly prescribed a diet from which all insoluble débris was removed as far as possible. That indication was met by recommending that all animal food should be passed through a mincing machine and all vegetable food through a fine sieve. If those conditions were observed the actual composition of the diet might safely be left to the choice of the patient. He was inclined to think, however, that in severe cases all animal foods, except milk, should be forbidden and that the diet should be a purely lacto-farinaceous one. He had known at least one case in which such a diet was observed for more than a year with the greatest benefit. He came finally to the consideration of operative measures. In intractable and old-standing cases which had resisted treatment, and where the patient was becoming more and more of a confirmed invalid, it was naturally asked whether any help was to be found in surgery. A temporary ascending colotomy had been recommended in such cases and practised with some success, but its inconveniences were very great. Ileo-sigmoidostomy appeared on the face of it to be a more rational proceeding, for it threw the colon out of action completely and permanently. His experience of that operation in muco-membranous colitis was limited to three cases. In all of those great improvement resulted and was maintained after the lapse of more than a year, but in none was there a complete cure. One patient, indeed, continued to pass considerable quantities of mucus in spite of the fact that the ileum had been detached from the cæcum and united to the lower part of the sigmoid flexure. He thought, therefore, that it would be well, where the absence of adhesions made it easy, to remove the entire colon in such cases in order to prevent the regurgitation of the intestinal contents into the cul-de-sac which remained when the large bowel was left *in situ*. That, as they knew, had been practised successfully by Mr. W. Arbuthnot Lane in severe cases of fæcal stagnation from atony and dilatation of the colon—a condition in which, as a matter of fact, muco-membranous colitis was often present as well. In two of Dr. Hutchison's cases appendicostomy was copious growth of Klebs-Löffler diphtheria bacillus was obtained from the cerebro-spinal fluid and almost a pure culture of the same organism from the material obtained from the heart. The diphtheria bacillus had evidently invaded the central nervous system and embolic plugs laden with diphtheria bacilli would be sufficient to account for the symptoms resembling cerebro-spinal meningitis. As Dr. Nash points out, this case suggests that isolated cases of death preceded by symptoms of cerebro-spinal meningitis should not be attributed to *epidemic* cerebro-spinal fever without adequate bacteriological proof. We agree with him when he says that to justify the diagnosis of epidemic cerebro-spinal fever it would appear to be quite necessary that the presence of the diplococcus intracellularis of Weichselbaum should be demonstrated. There are many interesting points in connexion with this case that are worthy of careful consideration, and Dr. Nash duly discusses some of them. Dr. W. Bulloch, who conducted the bacteriological examination, remarks that cerebro-spinal symptoms in association with malignant endocarditis have been formerly observed, but he is not aware that the diphtheria bacillus has previously to this instance been demonstrated as the infecting organism.

THE INTERNATIONAL STOMATOLOGICAL ASSOCIATION.

THE inaugural meeting of the International Stomatological Association was held in Paris on August 6th and 7th, immediately after the first French Congress of Stomatology. The officers of the association are as follows: Honorary Presidents: Professor E. S. Talbot (Chicago) and Dr. L. Cruet (Paris). President: Professor J. von Arkovy (Budapest). Vice-Presidents: Professor C. Redard (Geneva), Professor C. Platschick (Milan), Dr. Otto Zigmondy (Vienna), and Dr. Johan Rygge (Christiania). Secretary-General: Dr. H. Alleoys (Antwerp). Secretaries: Dr. J. Sim Wallace (London), Dr. J. Breitbach (Dresden), and Dr. D. Nicoleacu (Bucharest). Treasurer: Dr. F. A. Meyer (Amsterdam). In addition there is a representative council consisting of 20 members, each representing a different country. The officers and representatives are each elected for three years. The next meeting of the association will take place at Budapest in August, 1909, immediately after the Sixteenth International Congress of Medicine.

HYGIENE IN PRUSSIAN SCHOOLS.

THE Prussian Minister of Education has recently issued new instructions, in extension of those of July 14th, 1884, relating to the treatment of infectious diseases in schools. If they are observed the school premises will become one of the least likely sources of infection, for as a result of the war waged on microscopic germs cleanliness in the class-rooms and the lavatories and purity in the drinking water will be assured. The number of notifiable diseases has been increased by the inclusion of tuberculosis of the throat and lungs "so long as bacilli are present in the sputum." Teachers and pupils who have any doubt as to their health are earnestly requested to consult a medical man for the purpose of having their sputum examined. All pupils suffering from infectious disease are to be excluded from schools. Isolation is imposed on all who have been in contact with a patient and it extends to public places, playgrounds, and parks, in addition to school premises. When diphtheria breaks out in a school all who have been in contact with the patients are advised to submit themselves for treatment with serum. Daily disinfection of the throat and nose is recommended to persons who have been in contact with cases. In boarding-schools modifications of these rules are introduced, for it is felt that the closing of a boarding school is an effective method of spreading a disease, whereas the closing of a day-school may be a salutary precaution. Finally, it is recommended that in natural history lessons pupils should be given instruction in the treatment and care of infectious diseases. In the modern reading-books for continuation classes instruction in the simpler matters of hygiene is becoming a prominent characteristic and the children often carry the information to the parents whose aid the school is advised to seek in enforcing the new instructions.

THE ROYAL SOCIETY OF MEDICINE:

THE library of the society will reopen for the use of Fellows and members of sections on Tuesday, Oct. 1st. During the recess a considerable amount of work has been done, shelving for nearly 20,000 additional volumes has been provided, and the libraries of the societies which have combined have been brought together and conveniently arranged. A large portion of the premises hitherto let off to tenants has been taken over for the use of the society and many changes in the internal arrangement of the library have been made.

THE autumn meeting of the South-Eastern division of the Medico-Psychological Association will be held, by the courtesy of Mr. Reginald J. Stilwell, at Moorcroft, Hillingdon, Uxbridge, on Tuesday, Oct. 8th. Communications will be made by Dr. R. H. Cole on a Short Account of Moorcroft, Past and Present, and by Dr. W. H. B. Stoddart on Babinsky's Conception of Hysteria. The members will dine together after the meeting at the Café Monico, Piccadilly-circus, at 7 P.M.

A GENERAL meeting of the Association Internationale d'Urologie will be held on Tuesday, Oct. 8th, at 10 A.M., at the Hospital Necker, Rue de Sèvres, Paris, to decide upon the final constitution of the association. Delegates of the national committees alone have the right to take part in this. Any or all of the members of one committee can be present at the meeting and can take part in the deliberations, but each nation will only have one vote.

THE winter session of lectures and demonstrations at the Hospital for Sick Children, Great Ormond-street, London, will begin on Oct. 10th at 4 P.M., when Dr. A. E. Garrod will give a lecture on Diabetes in Children. On Oct. 17th at the same hour Mr. H. Stansfield Collier will lecture on Experiences of the Opsonic Method in Surgical Cases. Lectures will be given every Thursday at 4 P.M. and are free to all medical practitioners.

THE centenary of the Geological Society was held on Thursday, Sept. 26th, when an address was delivered by Dr. M. Grabham, as the representative of the Royal College of Physicians of London. To-day (Friday) the society visits St. Paul's Cathedral. We hope to publish Dr. Grabham's address in a future issue.

THE first Hunterian lecture of the Hunterian Society will be delivered on Wednesday, Oct. 9th, at 8.30 P.M., by Dr. F. M. Sandwith, Gresham professor of medicine. The subject is Dysentery. The meeting will be held in the London Institution, Finsbury-circus, and all members of the medical profession are invited.

THE annual presidential address will be given by the new President, Mr. R. Lake, F.R.C.S. Eng., before the West London Medico-Chirurgical Society on Oct. 4th at 8 30 P.M. at the West London Hospital, the subject being the Relationship of Disease of the Ear, Nose, and Larynx to General Medicine.

THE winter session of the West London Post-Graduate College will commence on Monday, Oct. 7th.

tuberculous focus in the lungs." Quite so; my idea is that every tubercle, active or latent, should be attacked or aroused and destroyed. That is why I suggested a prolongation of the ether saturation (if I may use the term) of the body in order that latent tubercle in hard structures may be reached. I did not suppose that it would be necessary to keep a tubercle long in direct contact with ether before it would be destroyed. Dr. Hemfeld alludes to "several instances where pulmonary tuberculosis has been seriously aggravated after operations performed under ether." It is only reasonable to suppose that if we are going to wake up latent tubercle in order to destroy it, that that tubercle is not going to take its execution lying down. Desperate diseases require desperate remedies, but even those remedies can be used with that consideration suggested in my previous letter.

I am, Sirs, yours faithfully,
ROBT. HUGH HODGSON.

Sept. 23rd, 1907.

REVALENCE OF BILHARZIOSIS IN THE ZAMBESI BASIN.

To the Editors of THE LANCET.

SIRS,—Since the discovery made by Bilharz Egypt has lways been considered as the favourite hunting-ground of chistosomum hæmatobium. After the same distome had een discovered by Harley at the Cape it could be presumed hat this malady, which raged at the two extreme ends of frica, would also exist in all the remaining parts of the ntinent. As a matter of fact, it has been met with in a rge number of countries but always appeared very much ss frequent than was the case with the Egyptians, as inted out as the result of investigations made by Bilharz, eisinger, and Sonsino. According to these writers, in at country half the inhabitants are affected with this sease, which has been confirmed by the congress recently Cairo (1902).

As regards the Zambesi basin it has been ascertained to ist there but in a vague manner. R. Blanchard remarks: Throughout the Zambesi basin the inhabitants suffer from ematuria and they ascribe the cause of this disease to worms hich they declare can be seen from time to time leaving them rough the urethra." Brandt remarks: "This complaint is und along the lower course of the Zambesi" (1900). trick Manson and other writers who wrote after them did t refer to the prevalence of this malady in the Zambesi sin. I have ascertained the existence of this complaint ong the lower as well as the upper reaches of this river, e characteristic eggs of bilharziosis being found in preparans of hæmaturic urine. But what appears to me the most teresting point is the extraordinary frequency of cases at st along the lower reaches of the river. Whilst in other rts of Africa cases are stated to be of small frequency or ought into the country from elsewhere, we have here fore us a veritable hotbed of endemic disease.

Notwithstanding the absence of statistical data, which nnot be supplied in those parts, I believe that bilharziosis st be in the Zambesi region of a frequency equal to that ich has been ascertained in Egypt. Chinde, Sena, and te, which are the principal posts on the banks of this river, infested with this disease, which particularly attacks les and most of all children. Europeans, thanks to their perior hygiene, enjoy immunity from it. I have observed considerable number of cases but I have only been able to llow nine of them (in all cases children). I have only served urinary bilharziosis but it is more than probable at in addition the other known localisations of the disease uld be discovered. I have used the Wortabel treatment th spirit of turpentine, to which I added thymol. The two dicaments were administered separately and successively t of six cases thus treated I obtained improvement as far pain was concerned in four cases.

I am, Sirs, yours faithfully,
FRANCISCO MORAES MANCHEGO, M.D. Lisbon.

ampo Maior, Portugal, Sept. 14th, 1907.

THE PREVENTION OF TUBERCULOSIS.—At the eting of the Newport (Mon.) board of guardians, held on pt. 14th, it was decided to fit up a detached house near workhouse for the treatment of cases of pulmonary berculosis.

THE PUBLIC AND PRIVATE SLAUGHTER-HOUSES OF DUBLIN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART II.[1]

The Private Slaughter-houses.

THERE is in Dublin an organisation called the Dublin Victuallers' Association, composed in the main of master butchers. Two of its members are on the Dublin town council and one of them, Mr. William Field, is a Member of Parliament. It is undoubtedly an influential body and I appealed to it for facilities to visit private slaughter-houses. My request met with a courteous and favourable reply and some members of the committee very kindly accompanied me round to a large number of private slaughter-houses. The first was in North Dock Ward. It was well organised and situated well away from dwelling-houses. Both the stable and slaughter shed had carefully cemented floors. A sliding door kept the animal about to be killed outside where it could not see what was coming. The second private slaughter-house was near the Great Northern Railway, down a court, but only a few steps from a broad, well-frequented road with a tramway in it. The slaughter shed was immediately behind a dwelling-house abutting on to this road. On the other side stood the barracks of a fire brigade. This slaughter-house was but a poor, badly lighted shanty much too near dwellings. The walls were whitewashed but there was no other protection and only one small window. The place was wretched but quite clean at the time of my visit. It could not be called a slaughter-house but merely a little hut quite unsuitable for the purpose, in which, nevertheless, animals are killed. The third private slaughter-house was like a little barn with a pointed roof. There was no protection for the walls—I mean no water-tight, washable dado. The part of the floor where the horned cattle fell was of flag-stones which, when struck with the horns, is less likely to break up than concrete. Here, also, there was but one very small window. For the living animals there were a stall in the open and plenty of open space but no proper pavement, only small round stones, and the manure and blood readily sink in between these. The fourth visit was to another oblong, barn-shaped structure, but here at least the walls were daubed over with the tar-like substance known as naphtha-black and thus were much better protected against the splashing. A house overlooked this slaughter-house but it was at a fairly good distance. The fifth slaughter-house visited took, I was told, one and a half hours to whitewash, and this was done once a week. It was also a very small place.

The proprietor of the sixth private slaughter-house which I visited was a man of enterprise; he had travelled, had been to America, and realised that slaughter-houses should be specially built. Therefore his slaughter-house has openings on all sides so as to give a through draught, but they are at a height of at least 15 feet. The workers are thus not inconvenienced by these currents of air. Then on the roof there is a louvred lantern with yellow-tinted windows, thus preventing the sun's rays gaining direct access to the meat and the butchers below. The lower part of the walls was of glazed bricks so that the fire-hose could be employed to wash them down. There were omnibus rails overhead to convey the carcasses along without effort. This slaughter-shed was, indeed, more modern, better built, and better ventilated than any one of the slaughter compartments into which the public abattoir is subdivided, except that for killing pigs.

We now went to the very heart of the city. Just by the side of the most celebrated thoroughfare in Dublin, Sackville-street, there is quite a nest of ramshackle private slaughter-houses. There is also a sort of "Petticoat-lane," or bazaar for second-hand objects of all sorts, a network of narrow passages where only pedestrians can pass and where the goods are displayed on stalls on either side. It is a poor, slummy district, ill-paved and not well frequented. Some of the low structures that apparently were originally intended for stables or coachhouses have been converted into shambles. Behind the first private slaughter-house visited in this district, but the seventh on my list, there still remained a dilapidated stable. Round small clean them and to renew the vacuum but the bandage was not removed during the hour. Some cases did well from the beginning. In others the sinuses closed only to reopen. In two cases the method had to be abandoned on account of the occurrence of considerable hæmorrhage. Histologically there were observed dilatation of the capillaries and lymphatics and increased migration of leucocytes. At first the amount of discharge considerably increased but later it diminished. In some cases, however, the increase persisted and this seemed to impair the patient's general condition so much that the method had to be abandoned. The following are some examples. A boy, aged eight years, had had tuberculosis of the hip and a sinus for five years. After a month's treatment the discharge diminished steadily and the child gained 11 pounds in weight. A boy, aged three years, had tuberculosis of the knee. A plaster apparatus was applied and a compression bandage was used daily for six months. During this time the child walked about as before the onset of the disease. Marked decrease in pain and increase in movement of the joint occurred although in the upper part of the joint an abscess developed which opened spontaneously three months after the onset of the disease. The treatment was continued and a sterile dressing was applied. Then the suction treatment was begun and the sinus closed 16 weeks later. The patient had about 15° of motion in the joint and continued to wear a knee-splint for protection. A boy, aged nine years, had for four years tuberculosis of the spine and for nine months a sinus which followed incision and drainage of a psoas abscess. The discharge was profuse. Suction treatment was begun. In about five weeks the discharge greatly diminished and the general condition much improved. Of 16 cases treated, marked improvement or healing took place in eight. In five there was no local improvement but weight was gained and the colour index of the blood rose.

HUMAN TERATOLOGY.

To Geoffroy Saint-Hilaire science owes the first really systematic study of monstrosities and anatomical malformations and his "Philosophie Anatomique" needs little more than supplementing to maintain the authority which it has hardly lost since its publication in 1818–20. No nationality is exempt from what the older investigators called "Lusus Naturae," the British Isles being not the least prolific in these phenomena. Scotland in the first decade of the sixteenth century anticipated China in the second decade of the nineteenth in producing "twins" like those called from their birthplace "Siamese." Buchanan in the thirteenth book of his "History of Scotland" describes this "*monstrum novi generis in Scotia natum*" as in the lower part of its body resembling a male child in no wise differing from the normal; but above the umbilicus the trunk and all the members were double, representing both sexes. "Id Rex," he tells us, "diligenter et educandum et erudiendum curavit; ac maxime in musicis, qua in re mirabiliter profecit." Nay (he proceeds), it mastered various languages, while the two bodies betrayed diverse wills and would sometimes fall out with each other. When they agreed they would hold a consultation in the interests of both. This, too, was remarkable, that any hurt to the legs or loins below was felt by both bodies, but when the hurt was inflicted above the pain evoked response in one body only. One of the bodies, he adds, died several days before the other, but the survivor gradually pined away. "Vixit id monstrum," he concludes, "annos XXVIII. Hac de re scribimus eo confidentius quod adhuc supersunt homines honesti complures qui haec viderint." In all this we seem to be reading an account of the "Siamese twins" who died in 1874, aged 63 years. Among contemporary nationalities Italy (as THE LANCET, in its Italian correspondence, has from time to time put in evidence) contributes the most numerous, as well as the most bizarre, specimens to the repertory of teratology. In the day now passing her professional journals record the following: In the Island of Sardinia a peasant woman, after prolonged labour lasting three days, was delivered of a gruesome monstrosity. The head of the child (male), normal in size and oval in contour, is without hair; the face is "framed," so to speak, with long hair; the eyes are in the middle of the forehead; the ears are absolutely wanting. In the middle of the thorax there is a "crocè" (cross) formed of hair which covers the backbone, the legs, and the arms, and is at once very long and fine. The hands are wanting. This monstrosity is still alive and the mother, who, it appears, has not yet been allowed to see it, is doing well. From the physical to the moral and intellectual monstrosity, says one of the commentators on the above, there is but a step—how short and how frequently taken let the criminal-lunatic asylums of Italy bear witness.

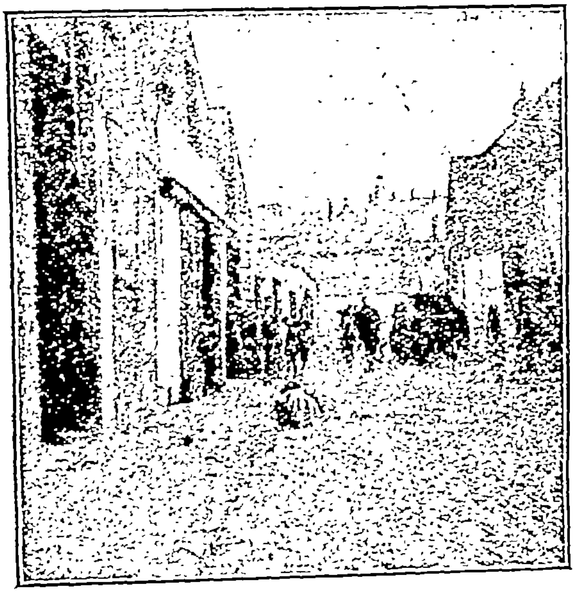
COÖPERATION FOR ASYLUM NURSES.

DURING the past two months there have been several notes in the *Nursing Times* on the subject of asylum nurses. Attention has been drawn to the fact that there is no coöperative nursing home for these nurses similar to those staffed by nurses who have been trained in general hospitals. We are aware that at least one nursing coöperation has asylum-trained nurses on its staff, but it would appear both in the interests of the public and for the better recognition of fully-qualified asylum nurses that a home should be started which shall only supply properly trained nurses who in return shall have the advantages of working under a coöperative system in the matter of their remuneration. We presume, as a guarantee that the nurses so supplied have attained a certain degree of efficiency, that they will be expected to hold some recognised certificate such as that granted by the Medico-Psychological Association of Great Britain and Ireland. We are informed that Miss Jean Hastie is starting early in October a "Mental Nurses' Coöperation" which, we understand, has the sympathy and support of several consulting physicians in psychological medicine, and if properly managed the scheme should prove a successful one.

DIPHTHERITIC ENDOCARDITIS.

IN THE LANCET of Sept. 21st, p. 826, we published an unusually interesting case of malignant endocarditis of diphtheritic origin recorded by Dr. J. T. C. Nash. The patient was a child between three and four years of age. The clinical history of the case is worthy of notice. The primary disease (diphtheria) was of so slight a nature that it had passed practically unnoticed. It was only on cross-examination of the parents of the child after a post-mortem examination had been made that it was ascertained that he had suffered from ear-ache and a discharge from the ear three weeks previously; sore throat, however, had never been complained of. Doubtless such slight cases, owing to non-recognition, may be the starting-points of severe epidemics. When brought under medical notice the boy had headache, loss of appetite, furred tongue, constipation, and a fugitive erythematous rash. The later symptoms of occasional delirium, restlessness, and tenderness along the back with a continuance of drowsiness, headache, and fever, had suggested the possibility of malignant endocarditis. 36 hours before death retraction of the head and strabismus, and later a petechial rash and slight opisthotonos, led to a suspicion of cerebro-spinal meningitis. At the necropsy on examination of the heart vegetations were found on the aortic and mitral valves. On bacteriological examination a stones let the filth through into the subsoil of the centre of Dublin. The eighth slaughter-house was in the same yard. The walls were only protected with whitewash and had many crevices in which dirt and organic matter penetrated and remained to decompose undisturbed. The ninth, close at hand, was somewhat better. The tenth, again, was deplorable and there were many rafters with much dirt and dust on them which could fall on the carcasses. (See Figs. 1 and 2.)

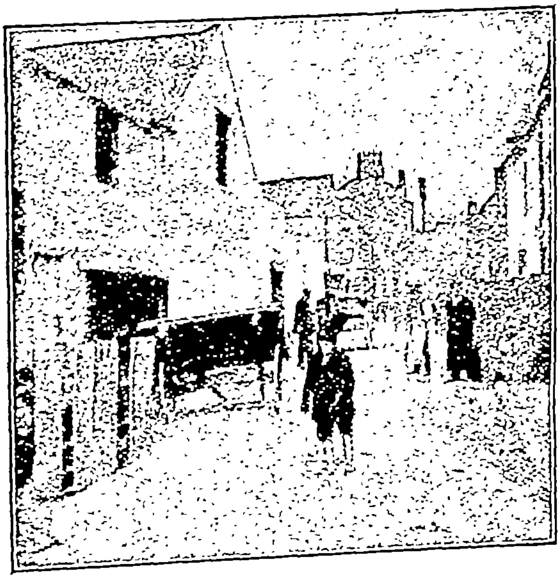
Fig. 1.



A court near Sackville street. The whitewashed buildings are slaughter-houses. The empty carts are waiting to convey meat. The blood often comes out on to the rough pavement where children play about.

On all sides I noticed many dead rats and innumerable living rats infest this cluster of slaughter-houses close behind Sackville-street. The private slaughter-houses are easy to recognise because they are all whitewashed.

Fig. 2.



A side street near Sackville-street. This is a thoroughfare where there are several whitewashed slaughter-houses.

The plentiful and constant use of whitewash is the main redeeming feature. Not only are these little buildings inadequate in themselves but the opening of the doors lets much of the dirt out on to the ill-paved courts or
streets. It is absolutely contrary to all principles aiming a
the aseptic preparation of meat for carcasses to be hande
about in these slums and close to the second-hand clothe
market with all its germs and dirt. Then here, as elsewher
and even in the municipal slaughter-house itself, there is th
abomination of the wooden tables riveted to a wall o
which the mesenteric fat is cut from the intestines. This
dirty work and the dirt locates between the wall and th
table, remaining there even when the table is washed. I
one or two places, however, instead of economising two leg
of the table by riveting it against a wall there were solid fou
legged tables which were not fastened to the wall and coul
therefore be moved and washed on all sides, and whic
when taken away did not prevent the washing of the wall.

The eleventh visit was in another thickly populated part o
the town. Here some ingenious lifting-pulleys were used
The floor consisted of six inches of concrete and one and
half inches of asphalt. This place had been recently built an
the best had been made of the crowded space but obviousl
slaughter-houses should not be behind shops in crowde
quarters. The twelfth visit was also to a slaughter-house o
the same premises as, and immediately behind, a shop o
the south side of the River Liffey. Here the killing is don
in a passage behind a very nice looking shop. There ar

stables and horses on one side of the passage. A litt
lantern roof to give more air and light has bee
built over the centre of this passage leading to th
street behind the shop. Everything was very clean b
cramped for want of space. The thirteenth visit was at
distance in the suburbs, not far from the exhibition. Her
there was more open space and dwellings were not so near a
hand, so some privacy and a good supply of air favoured th
butchers. The floors were cemented not only in th
slaughter-sheds but also in the stables.

The fourteenth and last visit was to the worst of all the
small private slaughter-houses. Down at the far end of a
ill-paved, dirty court there is a small, low structure. It h
no back windows and hardly any window space in fron
Within, innumerable corners, ledges, protuberances, an

a model abattoir might be and such knowledge cannot be

work, there was an increase in the number of patients admitted last year, 207 having been received "under the Act," and 267 as private patients by agreement with the licensees. It is mentioned that a revised code of rules has been prescribed by the Secretary of State which will permit of greater power being exercised by the central authority over the conditions under which patients are detained in licensed institutions.

In addition to the usual statistical tables the report is illustrated with an interesting series of plans of the certified reformatories of Ackworth, Lewes, and East Harling.

NOTES UPON HEALTH RESORTS.

FIUGGI: AN ITALIAN WATERING PLACE.

AMONG the watering places with which Italy abounds, and of which a description dealing only very summarily with each would form a large volume, there are but few which have achieved more than a local reputation. After mention of Montecatini, Sangemini, Salsomaggiore, San Pelegrino, and perhaps one or two others, the list of those familiarly known outside the country will be complete. This is not due to any lack of appreciation on the part of the Italians of the balneological resources of their peninsula, much less to any comparative inferiority in the waters themselves. On the contrary, the Italians have a strong belief, often amounting to a superstitious faith, in the efficacy of medicinal waters and during the summer are fond of combining with their usual villegiatura a visit to some of the numerous spas which are to be found in almost every part of the country. Many of these springs have a high medicinal value, their waters being constantly prescribed by Italian physicians with as much success as attends hydro-therapeutic treatment anywhere, and not a few of them if exploited with energy and enterprise would doubtless acquire the same wide reputation as is enjoyed, for example, by the best-known springs of France or Germany. Amongst those which will come prominently to the front when Italians awaken to this fact the waters of Fiuggi[1] near Anticola della Campagna[2] will take a high place on account of their efficacy in gouty complaints, and especially in the treatment of renal calculus and gravel. Their celebrity as a remedy in these affections dates at least as far back as the thirteenth century, when they were made personal use of by Pope Boniface VIII. for this purpose. This fame rests entirely on an empiric basis, for, curiously enough, a chemical analysis proves the water to be singularly free from the mineral constituents upon which the therapeutic activity of a water is supposed to depend, the solid ingredients contained in it amounting to only 0·058 gramme per litre, or about four and a half grains in a gallon. Nasini, who has lately made a careful physico-chemical examination of Fiuggi water, thinks that its medicinal powers reside partly in the element vanadium, of which it contains small quantities, but that they are also due in part to the radio-activity which it possesses to a degree unknown in any other drinking water and to the large amount of ozone dissolved in it. As the radio-activity disappears on boiling this property cannot come from radium itself, but must be derived from radium emanations in the contained gases. An examination of the surrounding rocks led to the interesting discovery that the tufa through which the spring issues is strongly radio-active, more so, indeed, than any other material hitherto found in Italy. Its radio-activity is, for instance, ten times as great as that of the "fango" or mud of Battaglia, and is due in part to uranium but also in part to radium.

The presence of ozone in the water, first observed by Cerasoli, is confirmed by Nasini, who, moreover, discovered that there is a large amount of the same gas in the vicinity of the spring, the quantity diminishing as the distance from the latter increases. He attributes its origin partly to the radium emanations in the water but principally to the action of the radio active rocks by which the atmospheric oxygen is partially transformed into ozone. Nasini attaches much importance to the well marked catalytic action which he has found Fiuggi water to possess and which he states to be unique in a water. He supposes this action to depend on the presence of vanadium and uranium which in the colloidal state are known to possess powerful oxidising properties even when present in quantities so minute as to be scarcely appreciable by ordinary chemical tests. But whatever may be the truth as regards the *modus operandi* of Fiuggi water, there can be no question as to its remarkable effects in cases of gout and especially of uric acid, gravel, and renal calculus. Professor Marchiafava's able assistant, Dr. Nazari, who has been for the past two seasons medical director of the "Stabilimento" of Fiuggi, reports a large number of cases which have come under his personal notice treated both at Fiuggi with water taken directly from the spring and in his Roman practice with the bottled water. Dr. Nazari believes that Fiuggi water may be regarded as an absolute specific for gout, and he even goes so far as to say that it may be used for diagnostic purposes in cases where the uric acid diathesis is suspected as the underlying cause of any illness. In typical articular gout and in renal calculus the beneficial results obtained both at the springs and at patients' homes are said to be quite surprising. In gout the salutary effects are not usually experienced until some time after a course of the waters, but in calculus the relief is often obtained within a few days after commencing the "cure," the gravel or stones being often voided without any pain.

The benefit frequently obtained from a residence at Fiuggi in other affections—such as diabetes, obesity, anæmia, hepatic troubles, skin complaints, neurasthenia, &c.—Dr. Nazari attributes more to the favourable conditions which prevail there in regard to temperature, radio-activity of the soil, the presence of ozone in the surrounding air, &c., than to the virtues of the waters themselves. The "season" at Fiuggi lasts from May to September and the "cure" for from 15 to 20 days or more. The water is drunk in the morning before breakfast, the patient taking from 10 to 20 glasses containing five ounces each at intervals of about a quarter of an hour. It is desirable at the same time to take gentle exercise in the form of walking or regulated gymnastics to help circulation and to promote the elimination of the water. Further doses should be drunk at meals and during the day. It is well to begin with a moderate amount, say five or six glasses, and gradually to increase it to an average of ten, or in some cases to 15 or even 20, glasses per day. Owing to its energetic diuretic action a large quantity of Fiuggi water may be taken without unpleasant effects if this rule be followed, but sometimes if drunk in excessive amount it gives rise to gastric pains and even to diarrhœa. On account of its purity and high degree of oxygenation it is a very pleasant water to drink and it seems to be equally efficacious whether taken as it issues cool and fresh from the spring or after it has been kept for some time in bottles. But it is doubtless best, whenever practicable, to drink the waters at their source where the climatic and other local conditions probably greatly favour their successful action.

When more comforts, and perhaps luxuries, than now exist have been provided for visitors Fiuggi will be admirably adapted for a summer resort, but the want of first-class hotel accommodation and of the other attractions which people are accustomed to find at a modern watering place must continue to limit its *clientèle* to a small class, and to repel the much larger number who prefer to combine with their pursuit of health a reasonable amount of pleasure and amusement.

ASYLUM REPORTS.

Royal Edinburgh Asylum (Annual Report for 1906).—At the beginning of the year 1906 there were 884 patients on the books of this institution but this number was reduced to 837 on Dec. 31st owing to the opening of Bangour Village. During the year 385 cases were admitted (169 males and 216 females), the total being 47 less than the average of the last five years, the falling-off being in rate-paid cases which were 54 below the average. Dr. T. S. Clouston, the physician-superintendent, states that only 35 out of the 385 patients admitted were in good bodily health, and that as many as 25 died within one month of admission. He further draws attention to the fact, which so many superintendents of asylums have recently noted, that the proportion of old and frail patients is steadily increasing year by year.

---

[1] Pronounced Few-gee.

[2] Fiuggi is not far from Frosinone on the Rome-Naples line and is reached from Rome in about five hours, two by rail and three by carriage.

conveyed in conversation. One butcher very justly remarked that the animals must rest before they are killed and be handled in a cleanly manner. If taken to the public abattoir rent had to be paid for them to rest and the master butcher could not be on the spot to see that his men did the work properly. Of course, in a model abattoir under the management of a veterinary surgeon living on the spot the most perfect cleanliness prevails and those who kill are under the direction and strict discipline of the sanitary authority, even if working for private butchers. The great idea was that if a butcher has a private slaughter-house just behind his shop he can kill when he likes, and as much or as little as he likes, according to the fluctuations in the demand for meat. He may want to kill only one animal and it would be a great loss of time to send all the way to the public abattoir. Then, if all the slaughter compartments were occupied he might have to wait a long time before being able to kill that one animal. Also, killing is hot work, and in cold weather it is a great risk for a man to drive outside a butcher's cart with the meat immediately after killing inside the hot abattoir. But there are, even at Dublin, two municipal slaughterers on the spot, employed by the town, and they could do all this retail work for the butchers without the latter having to send men from their shops for just one or two sheep. Then carcasses can be kept under better conditions at the abattoirs than in the small shops of the crowded districts. With properly constructed special vans to convey the meat to the shops it would be in such an excellent state that it would sell for a higher price. This is not a conjecture but what has actually occurred in many towns where model abattoirs have been constructed. The old-fashioned method of storing meat on ice is abolished and the customer soon perceives the improvement in the quality of the meat resulting from its more careful and scientific handling. From the public health point of view each animal must be examined and the carcass stamped by a veterinary surgeon before the viscera are removed. Of course, this is only possible in a public abattoir where the veterinary surgeons and their staff are on the spot at the killing hour. The stamping of the meat would do much to reconcile the Dublin butchers to modern methods. Their representative, Mr. William Field, M.P., has on several occasions attempted to introduce a Bill in the House of Commons for the stamping of imported frozen or chilled meat. At the same time home meat should bear the mark of the inspector. As the inspector could not be at all the private slaughter-houses the purchaser would be able to distinguish between imported meat, home-killed meat under proper inspection, and meat that had not been inspected at all.

Two main misconceptions stand in the way of effective reform. The butchers imagine that if they were compelled to go to a public abattoir this would cause them much extra labour and trouble, together with a considerable financial loss. Already the cry has been raised that if such a course was imposed then they must be compensated and apparently they imagine that they would be entitled to a large sum. Experience extending over several hundred towns shows that the reverse would be the case. But in ignorance of this fact another obstacle is created, and this time by the ratepayers. *They, on their side,* fear the increase of taxation so as to find means to construct model abattoirs and to compensate a large number of butchers. In answer to this it must be borne in mind that all experience proves that there can be no safer investment than a model municipal abattoir. However great the cost of construction and luxurious the installation, it pays interest on capital and provides for a sinking fund and often yields a considerable profit, thus helping to reduce instead of to raise the rates. The only condition of success is the absolute abolition of all private slaughter-houses.

The next question is the compensation to be paid to butchers, and where there is a genuine loss no one objects to compensation. In any case it is admitted by the German law, and we have before us the experience acquired in some 900 German towns. Of course, there must be a competent and impartial investigation, and then to what does it amount? At Gratz, in all, £160; at Dortmund, £690; at Kassel, £1050; at Magdeburg, £2100; at Kiel, £950; and so on. But at Dublin the position is quite exceptional, for if a complete model abattoir were established the advantage to the butchers would be so great that instead of giving them compensation they might very properly be called upon to contribute towards the cost of an enterprise destined to increase considerably their incomes. It is notorious that what pays best in public slaughter-houses is the utilisation of the by-products and the waste products. In Dublin this lucrative opportunity is wasted. The butchers do not even prepare tripe. Both from the public abattoir and from the private slaughter-houses all this is carted away. From the public health point of view this is most reprehensible. Obviously one of the principal reasons for establishing a public abattoir is to keep the control of *these by-industries which are dirtier and more likely to* create a nuisance than dealing only with meat under the direct control of the sanitary authority. Fortunately, it so happens that in this case there is complete harmony between financial interests and the interests of public health.

As the butchers of Dublin apparently do not know what to do with their by-products, do not possess the machinery and the technical knowledge for utilising them, this is an admirable opportunity for the town council. A model abattoir must be constructed with separate buildings on the same *grounds for the salting* and storage of hides, for cleaning, cooking, and *tying together* in bundles *the feet of sheep* and pigs; there must be a compartment for boiling calves' and other heads; then, far away, other departments for the *preparing of tripe, the cleaning* and *treating* of intestines to convert them into catgut or sausage skins; indeed, there should also be a pavilion for sausage making. *Then the blood must be utilised* on the spot and there must be a destructor to convert condemned carcasses into manure. In a word, nothing should leave the abattoir till it has been converted into a clean and saleable article. Even the manure should be an inodorous powder (*poudrette*). The most competent men of science and technicians should be obtained, if necessary from Germany, to organise all this. The moment the sanitary inspection of the slaughtered animal is over all the by-products would be conveyed to the different departments at once. After refunding the outlay the butchers would receive a good income from these by-products. At the same time they would realise something from the utilisation for other purposes, or from the sale, of the premises where their private slaughter-houses were situated. These two new sources of income would, in all probability, greatly exceed any extra expense entailed by having all their animals killed at the public abattoir. Dublin might then hope to place itself in this respect on a level with the 900 towns of Germany, not to mention towns of many other countries. The present deplorable and dangerous state of affairs cannot continue.

FOURTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE OPENING CEREMONY.

Berlin, Sept. 23rd.

EARLY this morning the Congress offices in the Reichstag were thronged with new arrivals inquiring about everything and with those who, having been here a day or two, had discovered that they were wanting in many things. There was the ticket for this entertainment, the subscription for such a banquet, and the supreme perplexity of selecting which of the many visits and excursions it would be best to undertake. Fortunately for the foreigner who could not speak German members of the organising committee and others willing to help bedecked themselves with a yellow ribbon if they could speak English and with a blue ribbon if they could speak French. Many among them proudly wore both colours and thus help was easily found by those who could not otherwise make themselves understood. Loaded with guide-books, lists of members, circulars, and much printed matter were the most recent arrivals as they crossed over from the Reichstag to the New Opera House where the opening ceremony was to take place. They had to pass the column of Victory and the statues of Bismarck and Moltke on their way, though some took the wrong direction and lost themselves in the shade of the fine trees that are the glory of the Thiergarten. The New Opera House

INSTITUTIONS FOR THE REFORM OF INEBRIATES.[1]

Dr. R. W. Branthwaite's report for 1906 comprises three sections dealing respectively with certified inebriate reformatories, State inebriate reformatories, and retreats. The first section occupies rather more than three-fourths of the volume and is that which presents most interest both to the medical and to the lay reader, as the institutions with which it is concerned, apart altogether from their utility in the treatment of inebriety, are well worth study for the sake of the lessons to be learned from them regarding the conduct of experiments in the care and control of the socially unadaptable classes. The account which Dr. Branthwaite gives of them will be read, moreover, with special attention at the present moment in view of the rather unfavourable criticisms which have been recently directed against the reformatory treatment of police-court drunkards.

During the year under review the number of persons committed to reformatories under the Act was 404, 294 women and 110 men, as against 352 women and 91 men in 1905 and 380 women and 33 men in 1904. The marked decline in the number of females is shown in committals under both sections of the Act, but is relatively larger in the committals under Section I.—that is to say, of women convicted of some form of indictable crime and sentenced to reformatory detention in lieu of, or in addition to, ordinary imprisonment. Dr. Branthwaite points out that this section of the Act has so far been applied chiefly to persons convicted of cruelty to, or neglect of, children. The operation of the Act in cases of this sort appears to be extremely satisfactory. In other indictable offences comparatively little use has been made of the powers conferred on the judicial authority under this section. As to the reasons for the decrease in the number of women sent to inebriate reformatories last year, Dr. Branthwaite suggests that the chief cause is to be found in the rather complicated safeguards with which the legislature in its excessive care for the liberty of the subject has thought it necessary to hedge round the procedure for the committal of a habitual drunkard. This applies particularly to section 2 of the Act which concerns the ordinary drunken recidivist of the police courts: before a committal under this section can be ordered by a court of summary jurisdiction it is necessary to prove the fact of habitual drunkenness, to show that the accused person has been convicted three times within 12 months of the specified offence charged, and to obtain his or her consent to be dealt with summarily. The effect of these restrictions is naturally in many instances to prejudice the magistrate against the novel and tedious method which is so encumbered and to make him prefer the quick and familiar way of sending the culprit to prison, especially if, as is frequently the case, he has but a limited faith in the power of reformatories to reform. The inspector does not say what alterations in this procedure he advocates, but he appears to entertain the opinion that there exists a category of police-court drunkards who cannot be reached by the law as it now stands but who if they could be brought under its operation would probably be curable by detention in a reformatory. Up to the present there has been no opportunity of testing the value of this method in cases not patently hopeless.

Having described very fully in his last annual report the mental and physical characteristics of the so-called "habitual drunkards" Dr. Branthwaite devotes most of his space in the present volume to an account of the machinery which has gradually been brought into existence for dealing with this very motley group of cases. It consists at present of ten certified reformatories and two State reformatories. Of the certified reformatories three were established by local authorities, six by philanthropic bodies and private persons, and one by local authorities in conjunction with private persons. Five of the six institutions in the second group are controlled by a single governing body working under the guidance of the Rev. H. N. Burden, to whose zeal and ability the inspector pays a well-deserved meed of praise. The centralised administration of these five reformatories (which are known collectively as "The National Institutions for Inebriates") has proved of immense value as a means o organising an adequate system of classification; it ha rendered it possible to arrange the several reformatories t meet the needs of different types of inmates, so that afte a probationary period in a receiving house the inebriate sent from the courts can be distributed according to th character and prospects of each individual case. Completed by the State reformatories for violent and unmanage able inebriates this system is found to work ideally In the reformatories founded by the local authorities on the other hand, the attempt to deal with all sort of cases in a single institution gives much less satisfactor results. Nor is this the only point in which the count council reformatories compare unfavourably with th national institutions; in the matter of economy the latte establishments show an enormous superiority. In the thre reformatories built by the local authorities the original cos averages £526 per bed, while in those belonging to th national institutions it amounts only to £112 per bed, and i the latest built, that at East Harling, it is no more tha £100 per bed. Even when full allowance is made for th fact that the local authorities have built with a view to th future expansion of their reformatories and have therefor provided an administrative installation largely in excess o their immediate needs, these figures assuredly suggest a unreasonably lavish expenditure, which is the less excusabl because, as the report informs us, it was incurred despite th protests of the inspector, who failed to see the necessity o oak panelled board rooms and tesselated pavements in asylum for the detention of criminal inebriates. If the accommodation provided at £112 per bed in the national institutions i adequate for its purpose—and we have Dr. Branthwaite' guarantee that it is so—it is difficult to see what end i served by expending four or five times that sum and s furnishing a valuable argument to the critics of the reformatory system. In respect of the cost of maintenance, again we learn that the centralised control of the reformatorie belonging to the national institutions makes for economy in these reformatories the expenditure per head is considerably lower, while the profit from the labour of the inmate is considerably higher than in the county reformatories. A Chesterfield, for instance, the most expensive of the reformatories of the former class, the total weekly maintenanc expenditure amounts to 12*s*. 6½*d*. per head and the ne proceeds from industries to 1*s*. 2½*d*. per head, while th corresponding figures for the Lancashire county reformator at Langho are respectively 14*s*. 8½*d*. and 8¼*d*. per head, an at Farmfield, the reformatory of the London County Council the cost of maintenance is 18*s*. 6*d*. per head and the ne value of the industries is *nil*. These points in Dr. Branthwaite' report are particularly deserving of attention because ther has been an evident disposition of late to take the Inebriate Act as a model in other and more extensive schemes fo dealing with the defective classes. It will be recalled, fo instance, that the Departmental Committee on Vagranc quoted the provisions of this Act as a precedent for it recommendations that the labour colonies which it advocated should be established and controlled by the count councils and not by the State, and, further, that the establishment of such colonies should not be obligatory on the councils. It is interesting, therefore, to observe that the difficulties in working the Inebriates Act have arisen largely from the very provisions which have thus been singled out for imitation. Local instead of centralised control has prevented proper classification and has increased expense in building and in up-keep, and the merely permissive character of the authority conferred on the county councils to found or to subsidise reformatories has encouraged the majority of the councils to leave the Act severely alone.

The report concerning the State inebriate reformatories mentions that up to March 31st, 1906, 234 inmates had been admitted to these institutions, 71 being males and 163 females. 16 of the total number were committed directly from assizes and quarter sessions under Section 1 of the Act and the remaining 218 were transferred from certified reformatories for refractory and unmanageable conduct The function of these State institutions is seen from these figures to be mainly that of a rubbish heap for the rest of the reformatory system. In view of the very defective mental condition of the majority of the inmates it is satisfactory to note that the administration of the larger of the reformatories, that at Aylesbury, is entirely under medical control.

With regard to retreats, of which there are 22 in regular is quite unlike the majority of opera houses. It is a square building with a broad gallery round three sides and a narrower smaller gallery underneath and in the shade of the greater gallery. The higher gallery is by far the best and thus are "the gods" exalted. But on this occasion there were no gods, only goddesses, for here were placed all the ladies. Before 11 o'clock there was scarcely any standing room remaining; from 3000 to 4000 persons must have been present. It was early morning, but the theatre was lighted up and everyone wore evening dress. Exactly at the appointed hour, 11 o'clock, His Highness the Crown Prince appeared in front of the huge royal box, his light-blue uniform contrasting with the deep crimson and heavy drapery of the box. He stood at attention as the President of the Congress delivered an address from the stage. Here sat in rows the official representatives of many Governments. The audience stood facing the centre of the building, so that they had the platform or stage on one side and the royal box on the other side, and it could not be said to which of the two they paid the most attention. When the President (Prince Heinrich zu Schönaich-Carolath) had finished his few words of welcome we were all invited to sit down. But we had hardly taken possession of our seats when the President proposed three cheers for His Imperial Majesty the Emperor and we had to rise again. After we had duly repeated "Hoch!" three times the band played one verse of the National Anthem, which is the same as the English anthem. The band, however, was somewhat brassy and I missed those original and beautiful harmonies introduced by the splendid band of the Garde Républicaine when they welcomed the British physicians and surgeons during their visit to Paris.

---

[1] The Report of the Inspector under the Inebriates Acts, 1879 to 1900, for the year 1906.

After this loyal display we definitely resumed our seats and patiently waited for the long flow of speeches. They were, indeed, very numerous but most of the speakers had the good sense to speak very briefly. The scenery on the stage, if I mistake not, represented the palace of Sanssouci, though this was scarcely felicitous for a congress which on the contrary is worrying over every detail of life so as to make quite sure nothing injurious to health shall be allowed. On the other hand, the front of the stage represented a wood and recalled the forest or recovery schools which honour the Berlin promoters of school hygiene. Then on the side of the stage stood the monumental statue of Hygeia especially made for the Congress by the sculptor, Georges Morin. From the galleries hung green garlands, while above fan palm trees drooped their branches gracefully over the ladies. The dark-green of this foliage contrasted with the lighter and more cheerful colours of the ladies' dresses and hats. It cannot be said, however, that the ladies displayed any startling toilettes, nor was there any sparkling show of jewellery. The men had to wear their best attire, though the ladies do not seem to have recognised any such obligation. But then, with wise economy, the women of Germany have refused to let the toilet question become the first consideration of existence. This demonstration of independence in regard to the dress tyranny comes appropriately at this moment, as it so happens that the old grievance of tight-lacing has just come to the front yet once more. A violent controversy on this subject is now engaging the press at large and strenuous efforts are being made to mitigate the evil. Of course, it is obvious which side sanitary reform will support.

After a few but well-spoken words from the Minister of State, Dr. HOLLE, Prince HEINRICH ZU SCHÖNAICH-CAROLATH, member of the Reichstag, member of the Herren-haus or Upper House, and President of the Congress, delivered a long speech which was translated into French by M. FUSTER (Paris). He pointed out that the object of the Congress was to serve all peoples by reducing the prevalence of sickness. The Romans had recognised the importance of hygiene, but in what darkness had they been enveloped since the fall of their great civilisation. However, hygiene had sprung to the fore again with such leaders as Pasteur, Lister, and Koch. Nevertheless, how great and profound was the misery that still remained. It was only necessary to visit any large town to see how much there was to be done and at the same time how many things were attempted. They would see the hospitals, the asylums, the sanitary institutes, and the public abattoirs. It was cheering to note also at these Congresses of Hygiene with what constancy men from all countries followed up from congress to congress the work attempted. Their efforts had led up to the conclusion of official international treaties in regard to precautions against epidemics, to labour protective legislation, and to the war against tuberculosis. The President also gave details of the immense sums spent under the compulsory insurance laws against accidents, sickness, and old age. Such labours were of benefit to all. To study hygiene meant to love your neighbour and to strive for human good.

Dr. BUMME, President of the Imperial Board of Health, spoke next and was followed by the general secretary of the Congress, Dr. NIETNER. Now came in rapid succession Professor WALDEYER, secretary of the Academy of Science; Rector KAFTAN who holds a chair of theology at the University of Berlin; Professor KRANZ, rector of the Technical High School; and Professor SCHMALZ, of the veterinary school.

After these German speeches we reached the international series, led off, on behalf of the French Government, by Professor CHANTEMESSE, of the Pasteur Institute. He was followed by Count DE SALIS, Councillor to H.M. Embassy at Berlin, who spoke as the official representative of the British Government, but he only said a very few words conveying the usual felicitations. Then came Dr. PAGLIANI for Italy, Dr. RITTER VON JURASCHEK for Austria, and another speaker for Hungary. A Japanese officer said a few words in French about the welfare of civilisation and Dr. BERTENSKY came forward as the representative of Russia. By this time the audience began to melt away. Dr. CORTEZO, having paid compliments on behalf of Spain, was followed by Dr. CHARLES HARRINGTON, Professor of Hygiene at the Harvard University, who said the United States Government had determined to invite the next Congress of Hygiene to cross the Atlantic and the city of Washington was impatiently awaiting their arrival. After four more speeches Dr. BARRERO rose on behalf of México and Dr. H. G. BORGESIUS for Holland. The Norwegian representative had a word next and then the delegate from Roumania delivered himself of a lengthy discourse. It was long past the lunch hour and more than half the audience had already disappeared when the Danish spokesman concluded the series of international congratulations and compliments.

His Highness the CROWN PRINCE was now at liberty to cross over to the Reichstag and to inaugurate the Exhibition of Hygiene. To-morrow the real work, the meeting of the sections, will begin. This afternoon the members of the Congress are visiting Berlin or examining the Exhibition of Hygiene.

THE EXHIBITION OF HYGIENE.

After the opening ceremony came the inauguration of the Hygienic Exhibition. This is held in the numerous lobby rooms, passages, corridors, and some of the committee rooms of the Reichstag. This massive pile, the German Houses of Parliament, of recent structure, built to house the representatives of a newly united Germany, is just at the beginning of the celebrated Thiergarten which constitutes the "Hyde Park" and "Kensington Gardens" of Berlin. Consequently, it is likewise close to the Unter den Linden, which is the Boulevard des Italiens of the Berliner. All the principal hotels are, of course, close to this choice district and therefore the members of the Congress will not encounter any topographical difficulties in visiting the exhibition or attending the meetings of the Congress. Of course, on the opening day there was but time for a superficial survey of the exhibition. Nevertheless, this sufficed to show its importance. Anyone with a taste for figures, statistics, diagrams, charts, and all kinds of devices to establish by optical means the comparative relationship of one disease to another, or of death to sex, occupation, age, &c., will find here the wherewithal for many hours of study. There are cubes of various sizes and colours showing at once the prevalence of this or that disease in some province, town, or country; also what happened before some special method of treatment was introduced and what has occurred since. On entering by the Brandenburger Thor I first came upon a marble bust of Prince Bismarck and on each side of it were elaborate exhibits of various systems of cremation as if the blood and iron statesman had specially advocated this method of disposing of frail humanity's mortal remains. One model showed a chapel with a place for the coffin on a trap door just before the altar. At a given moment the trap bolts are withdrawn and the coffin sinks out of view as if lowered into the earth. But below the chapel is the crematorium and, whilst the congregation is still praying, the body is consumed underneath. Here also are a variety of urns for the keeping of the ashes, and in a glass jar are shown the white clean ashes of a young woman, aged 18 remarks, these facts afford matter for grave reflection. The admissions responsible for the results are of labourers employed in European-owned estates who should be under careful management and supervision, and the diseases from which they suffer are easily recognisable and even preventable. The class of patients sent in consists of cases too serious for treatment on the plantations; they are for the most part very ill and in many cases too ill to admit of successful treatment. The following is a list of the principal diseases treated in the Negri Sembilan Government hospitals, with the mortality resulting therefrom: Malarial fever, number treated, 2545; deaths, 94; death-rate per cent., 3·6. Beri-beri, number treated, 1010; deaths, 75, or 7·4 per cent. Diarrhœa, number treated, 383; deaths, 126, or 33 per cent. Dysentery, number treated, 1252; deaths, 3,2, or 28 per cent. Pulmonary diseases, number treated, 379; deaths, 113, or 30 per cent.

PAHANG.

The general health was good throughout the year. The number of patients treated in the Government hospitals was [illegible], as against 2935 in 1905. The number of out-patients was 12,634, as against 13,610 in 1905. The prevailing diseases were malaria, dysentery, beri-beri, lung complaints, venereal diseases, and diarrhœa in the order named. The numbers of cases treated were 1221, 506, 449, 216, 208, and 127 respectively. Dysentery accounted for 125 deaths, beri-beri 76, lung diseases 51, malaria 35, diarrhœa 32, and venereal diseases 3. All these diseases, except lung diseases, show an increase when compared with the figures for 1905. The State surgeon writes: "The mortality from dysentery and diarrhœa was chiefly among Tamils. The Chinese, who rarely drink unboiled water and are generally more cleanly in their habits, seldom suffer from these diseases to any great extent. For dysentery cases a decoction of fresh mangosteen rind, made while the fruit was in season, was employed at Bentong with some success. Malarial fever shows an increase among all nationalities and the employment by the State of a large number of coolies during the past year has swollen the returns. A disquieting feature is the steady increase in the amount of venereal disease; the numbers shown, moreover, represent but a small proportion of those affected, the majority using local, and generally inefficient, remedies or being treated as out-patients. Beri-beri cases show a steady increase in the numbers admitted, though the percentage of deaths is but 16·92, as compared with 16·70 last year and 16·89 in 1904. Parboiled rice, when procurable, was issued and had, I consider, a beneficial effect."

MEDICINE AND THE LAW.

An Injured Knee as Stock-in-Trade.

AN extraordinary series of frauds appears to have been perpetrated by a man who has been sentenced to four years' penal servitude at the Central Criminal Court under the name of Ben Biten. He at some time sustained a perfectly genuine injury to one of his knees, the effects of which remained (and presumably remain) plainly visible. His method consisted in falling over any rope or open cellar-flap or similar obstruction for which he could claim damages against someone apparently responsible on the ground of negligence. It is not stated that he often had to bring these claims into court, but according to the police evidence he had made them on at least 50 occasions and in many instances had received as compensation sums varying from £15 to £50. His manner of earning a livelihood seems to have been a family secret, for he was discovered through his coming forward to swear that another man who went by the name of Burton was dead. This person had been charged with offences similar to those of Biten and, as a matter of fact, had failed to surrender to his bail and had escaped to America. Biten was Burton's brother and when he appeared in court to say that the latter was dead he was recognised by the medical officer of the Ocean Accident and Guarantee Corporation, which happened to be interested for the third time in defending a claim brought by him. He will now for some time be prevented from victimising his fellow-men, but his manner of doing so was attractively simple and medical men concerned in inquiring into claims such as he was in the habit of putting forward will no doubt make a note of his *modus operandi*.

Medical Evidence in India.

The position of a medical man in India when called as a witness on behalf of the prosecution in a criminal court apparently differs considerably from that of members of his profession in England or is not yet defined sufficiently clearly for all magistrates to be aware of it. In a recent case heard in the special magistrates' court at the Kolar Goldfields the defendant was employed in the mines and was charged with having caused an accident by his negligence. A medical man, one of the surgeons at the Goldfields, was called as a witness with a view to his giving evidence from the nature of the injuries of a coolie as to the probable manner in which they had been received. This he declined to do unless he were first paid the fee to which an expert witness would be entitled. The magistrate took the view that no such fee was payable in such circumstances on the ground that the witness was called in the interests of justice and was bound to give evidence accordingly, and on the witness still refusing to express his opinion he fined him 50 rupees, with the alternative of a week's imprisonment for contempt of court. The fine was paid but it is stated that there will be an appeal to the Madras High Court. It will be interesting to observe the result, for if the magistrate is right the law should be altered in favour of those whose profession renders them liable to be summoned as witnesses in many cases which otherwise would not concern them. If, on the other hand, the magistrate was wrong it seems strange that he should have been ignorant upon a point which might be expected to arise very frequently in courts of criminal jurisdiction. The paying for medical evidence in civil cases is a matter of arrangement between the medical witness and the party calling him.

Medico-Legal Experts in Paris.

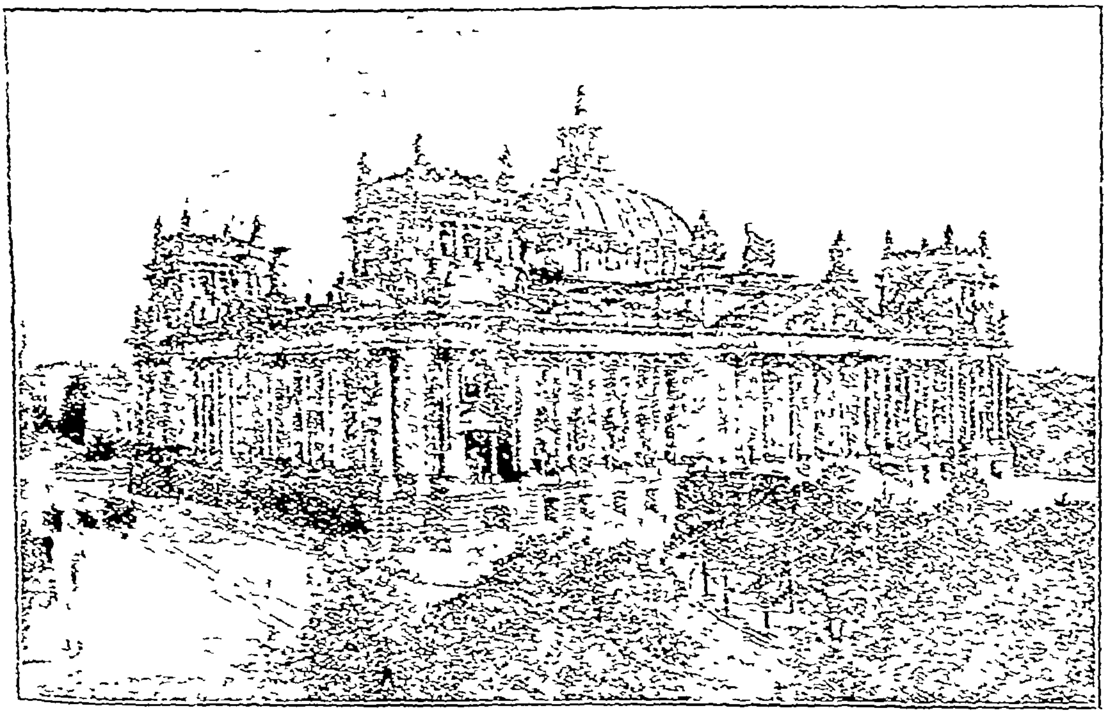
In view of the proposals occasionally made that medical assessors and experts should be attached to coroners' and other courts recent events in Paris in a similar connexion may be of interest. A few years ago a special course of practical and theoretical instruction was organised in Paris in order to prepare medical men to serve as medico-legal experts. About a score of candidates have now graduated and received the special diploma. A recent notice from the president of the civil courts bids the magistrates (*juges de paix*) at Paris to select their experts from the qualified list. In an editorial article in *Le Progrès Médical* a protest is made against this practice as being at once detrimental to the interests of justice and to the 450 medical men who have previously been called to give the expert evidence in these courts. It is affirmed that specialist expert testimony is essential—an ophthalmologist for diseases of the eye, a neurologist in nervous affections, and so on; no one human brain can have precise and specialist knowledge in all branches of medicine. The article deplores "the cultivation by the medical faculty of a parasitic flora of certificates and diplomas, sapping the vitality of the ancient trunk of the old-fashioned medical course still offered by the medical schools."

Bodily Illness as a Defence in Actions for Breach of Promise of Marriage.

In a recently reported case (Grover *v.* Zook) the Supreme Court of Washington decided that a breach of promise of marriage on account of tuberculous disease of the *fiancée* was justifiable, even if the matrimonial engagement was entered into with a knowledge of her condition. This American decision carries the legal attitude towards these contracts further than in any previously reported case, and while inflicting hardship upon the individual is doubtless directed towards protecting the public health. In 1886 in the Supreme Court of Pennsylvania a somewhat similar case was decided (Gruig *v.* Lerch). It was allowed to be a valid defence to an action for breach of promise of marriage that the plaintiff was incapable of performing the physical functions of marriage, which disability she had promised to have removed by a surgical operation before marriage, but had failed so to do. The English Court would not accept such defences where a simple contract had been entered into: Mr. Justice Matthew, on one occasion is reported to have said, "Love is not a necessary element in a breach of promise case," and Mr. Justice Vaughan Williams stated that bodily illness, while possibly being a plea against specific performance of the promise, was no defence against damages—for the *fiancée* may, as did Lady Teazle, "like to be a widow." The leading decision in our own records on disease years, who was cremated at Gotha. Close by is the reconstruction of a place for the preservation of urns which are attributed to an epoch that preceded the Slav era. Thus, the antiquity of the practice of cremation is practically demonstrated. The town of Hamburg shows its crematorium, as do several other cities. A few steps further and there is a table with all the reports of the Prussian statistical department, including a pamphlet on the hundredth anniversary of the existence of this office. Then comes a big stand of vital statistics and diagrams from Rio de Janeiro and immediately opposite is a similar exhibit from the Grand Duchy of Baden-Baden. The reason of such an unexpected juxtaposition is not given and I was left to wonder whether there was any more connexion between Bismarck and cremation than there is between Baden-Baden and Rio de Janeiro.

At this point and to the left there is a long narrow passage where all sorts of diagrams and pictures illustrate the working of the law for compulsory insurance against disease and accidents. Here are hundreds of photographs in large albums taken from life and illustrating all kinds of occupations where accidents may happen. Some photographs show what is defective and others how it can be remedied, and then statistics give the results attained. There are the actual figures and coloured designs or forms so that the proportional relationship of these figures may be realised at a glance. Taking up, as a sample, the first table to hand I found that it related to the accidents which had occurred in the building trades and on German ships in one year. Of these accidents 18,878 are described as inevitable and 9363 are attributed to want of skill. Want of guards—that is, the insufficiency or absence of guards or fencing of machinery—caused 3511 and deficient factory arrangements 3210 accidents. The accidents attributed to acting against rules amounted to 2442, and to the fault of a third person to 2570 The faults of employer and workman caused 2092, the failing to use guards 651 and insufficient instruction 826 The accidents caused by an inevitable outside force amounted to [illegible], carelessness or flightiness is responsible for 533, and badly fitting clothes for 220 more accidents Finally, there were 1075 accidents due to unascertained causes. It will be easy to understand that with details concerning all the trades given with equal amplitude year after year there should be no difficulty in ascertaining where are the weak points When the cause is known the remedy should be close at hand. The enormous masses of people comprised under the compulsory insurance laws of the German Empire provide for the whole world the most extensive and valuable statistics. The students of demography will be able to revel in this department and to find plenty of figures, especially in regard to trades and industries

In a narrow passage behind this there are many very fine wax models of various skin diseases, and in the broad Wandell-Halle there is a magnificent array of exhibits relating to bacteriology. Then we come to a rotunda where numerous exhibits dealing with the hygiene of school are to be found, such as furniture for growing children. There is the model of the Strasburg Hospital for Children, showing how it has been enlarged while still keeping plenty of garden space and trees. Near by is a life-size model of stall-like partitions made of enamelled iron and of large glass panes by which children in the ward of a hospital can be separated and yet all be kept in view of the attendant. In a side wing the war against tuberculosis is illustrated by models of sanatoriums. There is notably the miners' sanatorium at Sulzhayn in the Harz Mountains, North Germany. Here the galleries for the "air cure" are in the centre of the half-circle made by the building, the dwelling blocks being at each end. Above and below are woods of pine trees. There are models, also, of cottage sanatoriums, and, what I have not seen before, a large collection of lantern slides that would be very useful for lectures on the subject.



The Reichstag

What is called the Schreibsaal is devoted to exhibits of systems for the treatment of sewage mainly by processes of filtration intended to act bacteriologically on the sewage. Of course, there is a large plan of the Berlin drainage scheme and sewage farms. Many other practical exhibits are to be seen, such as the Clayton and other methods for killing rats on board ship, and a model of the warming and ventilating of the well-known German liner the *Kaiserin-Augusta* The members of the Congress when weary of hearing papers read in the sections may find the exhibition more interesting, and the sections meet where the exhibition is held, for the Reichstag is large enough to hold them both. For instance, pathologists will find in the exhibits of the Imperial Board of Health of Berlin much that is likely to attract their attention. Thus there are a number of beautiful preparations of the organs of various animals—cattle, rabbits, guinea-pigs, &c.—which had been infected with tuberculosis by subcutaneous and intravenous injection, by inhalation, and by feeding with pure cultures and with tuberculous material derived from both human and bovine sources. The detection and recognition of blood for forensic

The number of general paralytics gave a percentage of 14·2 on the admissions, the number of women so afflicted being in the proportion of 20 to 35 men, which is a very high one and is greater than for any other similar institution in Scotland. Dr. Clouston refers to the work of Dr. W. Ford Robertson and Dr. G. D. McRae on general paralysis. He says that "they have made distinct progress towards a knowledge of its true nature, its definite diagnosis, and, they think, of its treatment with a view to cure. The patients they have had under treatment have, where the disease was in an early stage, shown a wonderful improvement, but the first thing to be done is to be able to diagnose it definitely in its early stages, so that treatment may be applied before the brain is seriously damaged." ...... "Had we a sure means of diagnosing the complaint in its early stages there seems now good scientific reasons for the conclusion that it might then, under specific treatment, be arrested. The great hope for this lies in the fact that the new treatment is on the lines of modern pathological experience, being virtually on the same principles as the mode of treatment now commonly adopted in regard to diphtheria and such diseases as are caused by specific microbes." Passing on to consider other causes of disease in those admitted Dr. Clouston states that "alcohol was, as usual, the commonest of all the outward causes of the disease in those admitted. As a general assigned cause it is put down in our returns at 29·5 per cent. of the male admissions and 16·2 per cent. of the women. Taking that definite form of mental disturbance which we call 'alcoholic insanity' characterised by tremors, or paralysis, or hallucinations, or a marked loss of memory ...... the percentage was 18 among the male admissions and 10·8 among the females." There were 292 patients discharged during the year; of these 88 (33 males and 55 females) were "recovered," 156 (108 males and 48 females) were "relieved," and only 48 (32 males and 16 females) "not improved." A large number of "relieved" and "not improved" patients were transferred to Bangour Village. There were 140 deaths (55 males and 85 females), which gives a percentage of 16·2 on the average number of patients resident. Dr. Clouston states that the large number of cases of general paralysis, together with other fatal nervous diseases, accounts for the present high death-rate. The slight epidemic of colitis which began in 1905 has now died out, the West House drainage system having been repaired at considerable cost. The physician-superintendent goes fully into the question of tuberculosis in the Royal Edinburgh Asylum. He states that the pathologist to the asylum includes in the returns of death sent to the Scottish Board of Lunacy every evidence of unhealed tubercle detected and he adds that in the last Scottish Blue-book there are published the results of this notification for the five years 1901–1905. "The calculations are made, not as formerly, on the total number of deaths, but on the average numbers resident in each institution. I was much exercised when I found in that return that we stood at the top of the list of frequency in regard to our rate-paid patients. We were put down at 3·5 per cent. on the average number of such patients resident. The average of the rates for all other Scottish asylums was 1·58." He then fully discusses the figures and shows how deductions from them may prove fallacious and concludes his remarks by saying that: "(1) there have been no deaths from consumption at Craig House during the 12 years that it has been opened, and several cases who came in with its early symptoms have recovered; (2) the consumption rate among our West House private patients was under the average; (3) the consumption rate among our rate-paid patients at the West House has been over the average. I believe the cause of this has been the overcrowding of our wards of recent years." Dr. Clouston then briefly reviews the history of the institution since it received its Royal Charter exactly a century ago. The account that he gives is an intensely interesting one, showing, as it clearly does, the progress of the institution since its foundation. From the information available in the treasurer's statement it would appear that during the last 90 years about £370,000 have been spent on land and buildings, reconstruction and improvements. The total debt now stands at about £85,900, showing that £284,100 have been already paid off. The income from private patients has gone up from £12,500 to £38,000 per annum. Dr. Clouston further states that "the institution was in the beginning, and has always been, a great public charity, with no private profit accruing to anyone except the official salaries. Of recent years the legacies and subscriptions that have come to it have been accumulated as a charity fund, now amounting to £9600, the interest of which is applied to the reduction of the board of poor patients and the placing of educated rate-paid patients into the private wards, so that their associations may be more congenial and helpful to their recovery. In the year 1886 Mrs. Elizabeth Bevan, a grand-daughter of its founder, left to the institution the sum of about £13,000 for the purpose of supplementing the boards of patients of the educated classes. This legacy was made on the suggestion of Sir Arthur Mitchell. Through it and the charity fund about 80 patients in reduced circumstances year by year have received a benefit which largely conduces to their recovery and their comfort." In discussing the general history of the institution for the year 1906 he states that "we shall enter on a somewhat new phase of our work after this year through the removal of our Edinburgh rate-paid patients to Bangour Village. Hitherto the West House always contained more rate-paid than private patients; now the private patients will form the majority there. We shall from this time be able to admit all patients sent to us at £32 10s. and £45 rates of board. We shall then supply a much-felt need for our city and neighbourhood." The report also includes an interesting statement by Dr. P. H. MacLaren, the chairman of the ordinary managers of the Royal Edinburgh Asylum, and contains the usual statistical tables.

HEALTH MATTERS IN THE FEDERATED MALAY STATES.

SUBJOINED is a summary of the statements made in reference to health matters in the reports of the British Residents for the year 1906:—

PERAK.

The acting State surgeon, Mr. S. C. G. Fox, writes of the unsatisfactory way in which births and deaths are registered. The matter is in hand. In respect of births, the returns are inaccurate. In respect of deaths, the cause is wrongly given. To judge of the death returns from fever—5669 deaths out of 12,952—it would be presumed that Perak is a fever-stricken country. Everyone knows it is not; the diagnosis is to blame. One bad feature is that of infantile mortality; 1200 babies died under one year of age.

SELANGOR.

The large influx of Indian labour which took place in 1906 for work upon newly opened rubber estates has greatly enhanced the number of admissions to the district hospitals and has also been instrumental in raising the death-rate. A large number of the admissions were due to malarial fever and bowel complaints, for the most part contracted upon agricultural estates or by the members of working parties in outlying jungle country. Beri-beri has, on the whole, been less prevalent than usual throughout the State, the number of cases treated having been smaller in 1906 than in any period of 12 months during the last six years. Three cases of plague were treated, of which two proved fatal. In no instance was the source of infection discovered. Cholera occurred in seven instances at Port Swettenham, the victims being Indian coolies arriving on ships on which the disease had made its appearance. About 20 cases of small-pox occurred, approximately half of these being traced to infection on board the ship on which the patient had travelled from India. As a precautionary measure all coolies who do not show good vaccination marks on arrival are revaccinated before departure to the estates. Saigon buffalo lymph has been employed throughout the year and has been very satisfactory. If used within a fortnight of its arrival this lymph is quite the best the State surgeon has had any experience of in the East.

NEGRI SEMBILAN.

The number of admissions to Government hospitals during 1906 shows a large increase over that of 1905, the figures being 8567 and 6517 respectively. The number of persons treated as in-patients was 8948, as compared with 6924 in the previous year. The increase is in Tamil coolies from recently opened estates. The case-mortality rose from 7·9 per cent. in 1905 to 10·6 in 1906. When deaths occurring within 48 hours from the time of admission are excluded the figures for case-mortality are: 1905, 5·8; and 1906, 8·5. As the State surgeon purposes with the apparatus employed also forms an interesting exhibit, the method being the precipitation test of Uhlenhuth. By the same means horseflesh, for example, can be identified in sausages. A solution of the sausage is made by emulsification in water and to different portions of the solution the sera of rabbits which have been treated with emulsions of horseflesh, swine-flesh, goats' flesh, &c., are added. A white cloudiness or precipitate forms in the mixtures when the proteid emulsion comes in contact with the homologous serum. In the example quoted, a sausage made with swine flesh and horseflesh, precipitates occurred when the sausage emulsion was mixed with the serum of the rabbits which had been inoculated with swine flesh and with horseflesh but not with the serum of rabbits inoculated with other kinds of animal flesh. Materials, pieces of cloth, linen, &c., which had been examined for the presence of human blood stains were also shown.

The Imperial Institute for Infectious Diseases, Berlin, showed an extensive and well-arranged series of specimens, photographs, diagrams, and apparatus. Large plate cultivations of diphtheria, pseudo-diphtheria, and xerosis bacilli on litmus dextrose agar showed the differentiation of the diphtheria bacillus from the other two by the production of acid in the medium. A similar series showed the differentiation of the bacillus typhosus from the bacillus coli on litmus lactose agar. The method of typhoid enrichment according to the Lentz-Tietz method was also demonstrated. Inoculations from the stools are made in Löffler's malachite-green agar; this allows of the development and multiplication of the typhoid bacillus while inhibiting the growth of the colon bacillus, and by planting out the washings from the malachite-green plate after development on litmus lactose agar plates enables a plentiful growth of the typhoid bacillus to be obtained, the typhoid colonies producing no change in colour of the medium, while such colon colonies as there may be appear red. The differentiation of the various dysentery bacilli from one another and of the typhoid from the paratyphoid bacillus by the precipitation test with an immune serum of high potency was shown in a clear and conclusive manner. Specimens of therapeutic sera and of vaccines prepared at the institute were on view, also cases, preparations, and drawings of ticks, fleas, and blood-sucking diptera. Among the diagrams one showing that the incidence of malaria during different months of the year in Verona coincides with the prevalence of anopheles was of interest.

Sets of portable apparatus for establishing temporary laboratories for the campaign against typhoid fever, cholera, and plague were worthy of notice. Beautiful specimens of pure cultivations of micro-organisms and of the organs of animals which had suffered from the principal infective diseases were noteworthy. Plates of blood-agar inoculated with the staphylococcus aureus from the normal skin and from abscess pus showed that in the former case the organism produces hæmolysis and in the latter it does not, a point of some interest.

The exhibits of a chemical nature and apparatus associated with hygienic chemistry are naturally allotted a somewhat limited space in the exhibition. However, those shown in connexion with the Imperial Board of Health and appearing under paragraphs 34 to 37, p. 151, of the catalogue afford an excellent sample of the nature and scope of chemical investigation in its relation to general hygiene. The buildings of the Imperial Board of Health contain laboratories divided into separate rooms as follows: (1) general chemical laboratory; (2) food analysis laboratory; (3) balance room; (4) polarimeter and spectrometer room; (5) physical laboratory; besides rooms for high-temperature experiments, microphotography, and stores. With such an equipment every opportunity is afforded for the complete utilisation of analytical experiments for hygienic uses. Photographs of these laboratories are shown. Apparatus for the following processes are exhibited in the same recess: (1) estimation of small quantities of CO in air; (2) testing matches for white and yellow phosphorus; (3) the photographing of absorption spectra of blood; (4) collecting samples of air for examination for noxious gases; (5) the action of lead on drinking water—(*a*) apparatus for determining the extent to which a given water possesses lead-dissolving properties, and (*b*) for testing the action of lead-tin alloys in water; and lastly, the Polenske apparatus for determining volatile acids in butter. The Polenske apparatus is presumably devised as a modification of the apparatus in use for Reichert's process and differs from it in having an upright condenser and a bulbed tube with a more abrupt bend connecting the condenser and flask in order to allow for the erect condenser. The principal use of this process is to detect the presence of cocoanut fat in those butters which give a slight deficiency in the Reichert number, the further distillation of such samples showing the presence of non-soluble volatile acids which are absent from genuine butter fat. Actual adulterations are exhibited in the case of certain foods and drugs, the Halphen test for the presence of cotton-seed oil in butter, the appearance of copper-coloured gherkins contrasted with those not treated in that way, honey and moist sugar, and many other specimens. This exhibition if slight in itself is a valuable addition to the vast field of bacteriological technique shown in the surrounding recesses.

THE SECOND INTERNATIONAL CONGRESS OF "GOUTTES DE LAIT."

(FROM OUR OWN CORRESPONDENT.)

THE second International Congress of Gouttes de Lait was held in Brussels on Sept. 12th-16th, under the patronage of their Royal Highnesses the Prince and Princess Albert of Belgium. The Congress, the meetings of which were held in the Palais des Académies, was attended by over 600 delegates, including the official representatives of the Governments of the Argentine Republic, Bulgaria, France, Germany, Holland, Italy, Luxembourg, Norway, Roumania, and Spain. The delegates from Great Britain numbered about 40, representatives being present from the municipalities of Birmingham, Glasgow, Hampstead, Huddersfield, Hull, Liverpool, Manchester, Newcastle, and Woolwich. The President of the Congress was Dr. A. Devaux, Inspecteur-Général du Service de Santé Civile et de l'Hygiène of Belgium, and the secretary was Dr. Eugene Lust, the general secretary of the Ligue Nationale Belge pour la Protection de l'Enfance du Premier Age.

At the first International Congress of Gouttes de Lait, which was held in Paris in 1905, the discussions were almost exclusively confined to the work of the Goutte de Lait; the scope of the Brussels congress, however, was much more extensive and comprised the whole question of the prevention of infantile mortality. It was decided, moreover, that the scope of future congresses should be similarly extended and that they should be given a new name of wider significance. But it was thought advisable to retain the term "Gouttes de Lait," without translation, in the official title of the Congress, which will henceforth be called the "International Congress of the Protection of Infant Life (Gouttes de Lait)."

The "Goutte de Lait."

The work of the Goutte de Lait, in its various aspects, formed one of the chief subjects of discussion at the Congress. The Goutte de Lait, which is perhaps the most popular of continental institutions for the prevention of infantile mortality, is represented in our own country, in a modified form, by the infants' milk depôts that have of late years been established by several of our municipalities. It is practically a milk dispensary from which babies are fed under regular medical supervision during the first two years of life. Mothers are induced to attend the Goutte de Lait once a week so that their babies may be weighed and examined by the medical man in attendance. The mother is encouraged in various ways to suckle her baby, but if this is impossible she is supplied every day with specially prepared infants' milk in bottles, each bottle containing the proper quantity for one meal. The mothers are carefully instructed in the practical details of infant management, the chief object being to make the Goutte de Lait a school for mothers. There are now over 20 Gouttes de Lait in Brussels, most of which were established by the Ligue Nationale Belge pour la Protection de l'Enfance du Premier Age.

Some of the Brussels Gouttes de Lait are practically well-equipped out-patients' departments. At Dr. Lust's Goutte de Lait in the Place des Martyrs there is a serviceable laboratory where periodical examinations are made of milk, urine, stools, &c. Special attention is paid to nursing mothers. The mother's state of health is ascertained, her teeth are examined by a competent dentist, and any digestive disturbances are carefully attended to. If for any reason the mother appears to be losing her milk prematurely the cause is sought and, if possible, removed. Should the mother herself be insufficiently fed the Goutte de Lait, epidemic diseases was registered last week in Reading, [illegible], or West Bromwich, and only one in each of 11 other towns; the annual death-rates therefrom, however, ranged upwards to 3·7 in Gateshead, 3·8 in Aston Manor, 3·9 in Stockton-on-Tees, 4·4 in West Ham, 6·2 in Liverpool, 6·3 in Sheffield, and 7·4 in Warrington. The deaths from diarrhœa, which had risen from 39 to 278 in the ten preceding weeks, further increased last week to 397, the highest death-rates from this cause being 3·0 in West Ham and in Stockton-on-Tees, 3·1 in Aston Manor, 3·3 in Devonport, 3·9 in Bootle, 5·2 in Warrington, and 5·4 in Salford. The fatal cases of whooping-cough, which had been 76, 80, and 95 in the three preceding weeks, declined to 90 in the week under notice, and caused death-rates ranging upwards to 1·2 in Wigan, 1·4 in Ipswich, in King's Norton, in West Hartlepool, and in Merthyr Tydfil, 1·7 in St. Helens, and 2·0 in Great Yarmouth. The 49 deaths from diphtheria exceeded the number in any previous week of this quarter, and included 15 in London, four in Birmingham, and two in each of eight other towns. The fatal cases of measles, which had declined from 102 to 35 in the five preceding weeks, rose again to 43 in the week under notice; the highest death rates from this disease were 1·1 in Newcastle-on-Tyne and 1·4 in Cardiff. The 31 deaths from scarlet fever slightly exceeded the number in the previous week and included 13 in London and two each in Liverpool, Birmingham, and Sheffield. The fatal cases of "fever," which had been 13 and 12 in the two preceding weeks, rose again to 20 last week; the greatest proportional mortality from this cause was recorded in Bootle, where the rate was 1·6 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital at the end of last week was 4021, against numbers which had increased from [illegible] to 3572 in the 19 preceding weeks; the new cases admitted, which had numbered 557, 537, and 574 in the three preceding weeks, rose to 636 in the week under notice, and exceeded the number recorded in any previous week. The deaths in London referred to pneumonia and other diseases of the respiratory system, which had been 116 and 122 in the two preceding weeks, further rose last week to 130, but were 18 below the corrected average number for the corresponding period of the five years 1902-06. The causes of 36, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 50 other of the 76 towns; there were six uncertified deaths in Liverpool, five in Sheffield, four in Birmingham, three in South Shields, two in Preston, and two in Bootle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·6 and 15·3 per 1000 in the two preceding weeks, declined again to 13·3 per 1000 in the week ending Sept. 21st, and was 0·2 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 7·5 in Leith and 10·5 in Perth to 14·2 in Dundee and 15·2 in Glasgow. The 452 deaths in these towns last week were 70 fewer than the number in the previous week, and included 51 which were referred to the principal epidemic diseases, against 58 and 69 in the two preceding weeks. These 51 deaths were equal to an annual rate of 1·5 per 1000, which was 0·5 per 1000 below the mean rate last week from the principal epidemic diseases in the 76 large English towns; they included 27 which were referred to diarrhœa, ten to whooping-cough, six to "fever," four to measles, three to diphtheria, and one to scarlet fever. The fatal cases of diarrhœa, which had been 22 and 20 in the two preceding weeks, rose again to 27 in the week under notice, and included 21 in Glasgow, two in Dundee, and two in Paisley. The deaths from whooping-cough, which had been 22 and 18 in the two previous weeks, further declined last week to 10, of which four occurred in Dundee, three in Glasgow, and three in Edinburgh. The fatal cases of "fever," which had been 11 and 22 in the two preceding weeks, fell again to six last week, and included three in Glasgow and one each in Dundee, Aberdeen, and Paisley; all these six deaths were stated to be from cerebro-spinal meningitis. Of the four deaths from measles, three occurred in Glasgow; and two of the three deaths from diphtheria were recorded in Dundee. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 57 and 61 in the two preceding weeks, further rose to 67 in the week under notice, and slightly exceeded the number in the corresponding period of last year. The causes of 14, or 3 per cent., of the deaths in these eight towns last week were not certified or not stated: in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 20·7 and 17·6 per 1000 in the two previous weeks, rose again to 18·6 per 1000 in the week ending Sept. 21st. During the first 12 weeks of the current quarter the death-rate has averaged 18·7 per 1000, the rate during the same period being 12·0 in London and 12·5 in Edinburgh. The 139 deaths of Dublin residents registered during the week under notice were seven in excess of the number in the previous week, and included 13 which were referred to the principal epidemic diseases, against 12 and 15 in the two preceding weeks; of these, ten resulted from diarrhœa, two from diphtheria, and one from whooping-cough, but not any from small-pox, measles, scarlet fever, or "fever." These 13 deaths were equal to an annual rate of 1·7 per 1000, the death-rate during the same period from the principal epidemic diseases being 1·7 in London and 1·1 in Edinburgh. The deaths from diarrhœa, which had been eight, five, and nine in the three preceding weeks, rose to ten in the week under notice, while the two fatal cases of diphtheria corresponded with the number in the previous week. The 139 deaths from all causes in Dublin last week included 36 of children under one year of age and 35 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the previous week, while those of elderly persons showed a slight decline. Four inquest cases and four deaths from violence were registered during the week; and 57, or 41 per cent., of the deaths occurred in public institutions. The causes of seven, or 5 per cent., of the deaths in Dublin last week were not certified; in London only one uncertified death was registered, while in Edinburgh the proportion was equal to 6·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: P. H. M. Star to the *President*, additional, for three months' course at West London Hospital; T. W. Philip to the *Russell*; and W. H. Pope to the *Topaze*. Surgeons: A. R. Thomas to Plymouth Hospital, and A. B. Marsh to the *Ariadne*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Winfrid K. Beaman, from the seconded list, to be Lieutenant (dated Sept. 1st, 1907).

Lieutenant-Colonel M. Dundon has been appointed to the medical charge of the troops at Winchester. Lieutenant-Colonel J. M. Jones is placed under orders for India. Lieutenant-Colonel J. R. Dodd has been transferred from Dublin to Belfast as administrative medical officer. Lieutenant-Colonel H. N. Thompson has joined at Aldershot for duty at the Cambridge Hospital. Major G. T. Rawnsley has joined the Aldershot Command and been appointed to the medical charge of troops at Longmoor, vice Lieutenant-Colonel R. J. Geddes, D.S.O., transferred to the Military Hospital, Woking.

ARMY MEDICAL RESERVE.

Walter George Hughes Cable to be Lieutenant on probation (dated Sept. 2nd, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Suffolk and Harwich: Surgeon-Captain A. Y. Pringle resigns his commission (dated Sept. 1st, 1907). *Rifle*: 1st Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant E. R. Hunt to be Surgeon-Captain (dated August 3rd, 1907). 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal acting on the principle that the best method of "humanising" cow's milk is to pass it through the human mother, supplies the mother with milk for her own consumption at a nominal price. All the mothers are furnished with booklets and cards on infant feeding and management, and the printed directions are supplemented with careful oral instruction. Dr. Lust's Goutte de Lait is much frequented by medical students, nurses, and teachers who wish to gain practical experience in infant hygiene.

The Congress decided that the Goutte de Lait was an institution of great value generally both for breast-fed and for hand-fed infants, and that it formed an effective measure for the prevention of tuberculosis.

Infantile Mortality Statistics.

A valuable series of papers was submitted relating to the infantile mortality statistics of 14 countries. The chief fact brought out in these papers is that the systems of birth and death registration adopted in the different countries are so diverse that it is practically impossible to compare the infantile mortality rates one with another. The main point of divergence is the registration of still-births. In some countries, as in England, still-births are not registered at all. In others a child is said to be still-born when, although born alive, it has failed to survive longer than 24 hours. The Congress decided, on the motion of Dr. DIETRICH (Berlin), that a committee should be appointed to consider the best means of establishing a trustworthy basis for precise and uniform international statistics of infantile mortality.

Infant Feeding.

An interesting discussion took place on a paper on the Regulation of Infant Feeding by Dr. SIEGERT (Cologne). Dr. Siegert contended that the method of feeding an infant every two or two and a half hours was without physiological justification and that in practice better results could be secured by allowing an interval of nearly four hours to elapse between each meal. He held that suckling every two hours led to the exhaustion of the mother and to the impoverishment of her milk and consequently to the premature discontinuance of breast-feeding, and he thought that many mothers who now prematurely weaned their babies would continue suckling with excellent results if they were advised to give the breast every four hours instead of every two. Dr. Siegert's views gained considerable support but there were many dissentients.

Milk-supply.

The control of the milk-supply was one of the most important subjects discussed at the Congress and an excellent series of papers was submitted relating to the regulations in force in different countries for the control of the production and distribution of milk. From these papers, and from the discussions to which they gave rise, it was evident that in no country could the control of the milk-supply be considered satisfactory, and there was a general feeling that much more stringent measures were necessary. Mr. NATHAN STRAUS, who for the past 15 years had been supplying pasteurised milk at a nominal price in the poorer districts of New York City, submitted a paper in which he advocated the compulsory municipal pasteurisation of milk. Mr. Straus holds, as a result of his 15 years' practical study of the milk problem, that the "only safe rule is—pasteurise the entire milk-supply and make it a function of the municipality."

Mr. Straus's proposal of compulsory pasteurisation was opposed by Dr. HENRY J. COIT (Newark, N.J.) in his paper on the Development of the Pure Milk Movement in the United States. Dr. Coit contended that compulsory pasteurisation was undesirable because "it would remove the incentive to the public to compel, and to the producer to accomplish, improvement, and so postpone the time when a uniformly pure milk-supply would be available to the masses," and also because "pasteurised milk in bulk is not only intrinsically less desirable than clean raw milk, but is actually unsafe unless it is consumed within 24 hours and is kept constantly at or below 10° C." He thought that the general milk-supply could best be protected by the following measures: "(1) By proper legislation, looking to the elimination and eradication of tuberculosis and other serious diseases of cattle and the exclusion of persons having infectious or contagious diseases from any connexion with the production or handling of milk. (2) By thorough inspection of the sources of milk production, handling, and shipping; by care in the sterilisation of containers; by insuring proper cooling directly after milking and its constant maintenance till delivery to the consumer; by securing sanitary conditions in all places where milk is exposed for sale and the washing of all receptacles immediately after being emptied."

Dr. Coit, who is the President of the American Association of Medical Milk Commissions, gave an interesting account of the "certified milk" movement in America, which he originated in 1893 in Newark, N.J. "Certified milk" was milk that was certified by a voluntary commission of medical practitioners to be produced in accordance with a stringent code of sanitary requirements laid down by the commission. 27 medical milk commissions had now been organised in the principal cities of the United States. The work undertaken by these commissions was as follows: "First, to establish correct clinical standards of purity for cow's milk; second, to be responsible for a periodical and personal inspection of the dairy or dairies under its patronage; third, to provide for bi-monthly expert examination of the dairy stock by competent and approved veterinarians, and for medical supervision of the employees by competent physicians. The milk produced is subjected to periodical chemical analysis and to bacterial counts made under the direction of the commission as often as in its judgment is desirable." The expense of the examinations and inspections was defrayed by the dairymen supplying the certified milk, but the members of the commission received no remuneration for their services.

To many members, however, it appeared that it was hopeless to expect private enterprise to fulfil all the conditions necessary for the adequate protection of milk against contamination and at the same time to supply milk at a sufficiently low price to keep it within the reach of the poor whose present consumption of milk is far too small. The view was expressed that the only solution of the problem was to be found in the municipalisation of the milk-supply. In this way the rise in the price of milk could be prevented, for the municipality, working on a large scale would be able to effect such economies in delivery cartage, and in other processes of distribution as would neutralise the increased expenditure necessitated by the observance of the strict regulations and precautions required by modern sanitary science. A proposal in favour of the municipalisation of the milk-supply was moved by Dr. ENSCH (Schaerbeek, Brussels), and seconded by Mr. F. LAWSON DODD (London). It gained considerable support but was not carried.

The Popularisation of Infant Hygiene.

On the last day of the Congress an instructive discussion took place on the methods employed in different countries for the dissemination of information relating to infant feeding and infant management. Dr. S. G. MOORE (Huddersfield) gave an account of the system of health visiting adopted by many of our sanitary authorities, and he explained how this work would be facilitated by the Notification of Births Act which Mr. John Burns succeeded in passing through Parliament last session.

Dr. COIT gave a brief *résumé* of the health visiting work which is now being carried on with so much energy in New York City, both by the city health department, through its summer corps of physicians and nurses, and by the New York Association for Improving the Condition of the Poor. This association has been enabled by Mr. John D. Rockefeller to employ a large body of trained nurses who, during the past summer, visited 100,000 families, "giving the mothers actual demonstrations of how to bathe, dress, and feed their children, and in cases of illness to care for them in their own homes or in a summer hospital provided by Mr. Rockefeller for their use."

Miss M. G. TAYLOR (Manchester) briefly explained the methods adopted in the Manchester elementary schools for instructing the older girls in the hygiene of infant life. Miss Taylor gives a practical course of instruction to all the older girls in the schools. The course consists of six lectures with practical demonstrations, two lectures being devoted to teaching how a baby should be washed and dressed, two to infant feeding, and two to the general management of infants.

Several teachers took part in this discussion which ended in a short and animated debate arising out of a motion proposed by Dr. WINOCOUROFF (Odessa). This motion was to the effect that the popularisation of infant hygiene was only possible on the condition that the instruction given was accessible to the mass of the population and that the point of departure in all measures for the prevention of infant mortality was "l'instruction générale et obligatoire." M. RENE HENRY, the editor of the *Journal de* in the defendant being set up as a defence to an action on a contract to marry is the case of Hall *v.* Wright (1859), where failure of health owing to pulmonary tuberculosis was pleaded in vain as an excuse for the failure of the man to keep his promise to wed. The principles which obtain in such an alleged impossibility or undesirability of fulfilling the matrimonial contract may be analysed from the point of view of the defendant. Since one of the primary objects of matrimony is, in the words of the Book of Common Prayer, "for the procreation of children," such an objective may become impossible or its consummation very dangerous to either party should the defendant's health have been materially affected by a disease. On the other hand, the disease may make matrimony impossible or dangerous to one party only to the contract In the latter case several alternatives present themselves. The presence of the disease may be known to the defendant at the time when the contract to marry was entered into, it being reasonably thought that the malady was curable; the recent decision cited above shows that logic compels the recognition of the validity of such a defence by courts which would protect the defendant whose disease was only discovered subsequently to the engagement. Should there be no reasonable ground to think that the position will be altered before the marriage ceremony is performed, as, for instance, where a married man proposes to a spinster, the defence of obvious impossibility is futile. There remain the cases where the disease appears subsequently to the time when the contract was entered into; here the defendant may be disabled owing to his own fault, as where he has contracted syphilis or gonorrhœa, or he may have been infected innocently, as with pulmonary tuberculosis. In the former case no defence could be allowed on that account. In the latter case the English courts likewise decline to allow the supervening pathological circumstance to excuse the fulfilment of the promise, for it is held that the performance is not necessarily impossible, and even if it was impossible the plaintiff could still enjoy the social position which would result from the matrimonial alliance. The cautious wooer, if not going so far as to mark his letters "without prejudice," would insert in his proposal a proviso as to the possibility of a change of bodily health in either party, or perhaps would suggest that a satisfactory medical certificate should be produced by each party before the wedding day was named.

The Sale of Poisons.

At the Westminster police court recently Mr. R. A. Robinson, trading as Malden and Co., was summoned under the Pharmacy Act, 1868, for selling strychnine without observing the precautions required by the statute. The poison was supplied by the defendant's firm in the form of tabloids, as in the case described in THE LANCET of Sept. 7th, p. 729, and the prosecution was at the instance of the defendants upon that occasion, who apparently desired to retaliate thus upon the Pharmaceutical Society. Mr. Robinson was recently its President, although he did not hold that office at the time of the prosecution of Boots' Cash Chemists, Limited. Argument took place as to whether the latter as a corporate body could act as common informers, but the magistrate decided to hear the case, and after it had been opened the defendant, who appeared by counsel, entered a plea of guilty and was fined £3, with £2 2*s*. costs upon each of three summonses. These two prosecutions should have a good result if they check the unrestricted sale of dangerous drugs to persons who, though not desiring to make any illegal use of them, would act more wisely in not trifling with them. They should wait to obtain them until their use is ordered by a medical practitioner.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—The Chesterfield lectures of this hospital will be resumed at 49, Leicester square, on Thursday evening, Oct. 3rd, at 6 P.M., when the Chesterfield lecturer, Dr. Morgan Dockrell, will give the opening lecture on "The Present Position of Dermatology" The lectures will be given every Thursday up to March 19th, with the exception of a break at Christmas. After each lecture demonstrations will be given on special cases, followed by clinical instruction up to 8 P.M. on patients presenting themselves in the out-patient department. The lectures are free to medical men on presentation of their cards and to medical students who wish to attend regularly.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 26th, 1829.

STONE BULLET SHOT INTO THE BLADDER.

By WILLIAM LEWIS, *Esq. Surgeon.*

JOHN RODEN, a boy about 11 years of age, (of the Deanery-row,) of a spare habit and pale complexion, received a shot wound on the 5th of November last, while passing a door from behind which a pistol was discharged, loaded with a stone bullet; the shot, after penetrating the door, entered the upper part of the left thigh, and afterwards passed *into the bladder*. On my first visit, I found a contused wound of a circular shape. I extracted several small pieces of wadding, but was not able, by the most minute examination, to detect the presence of any other foreign body. Syncope supervened, although the hæmorrhage was slight, *and no urine passed* through the wound at that time. On the following day, there was *great external inflammation* about the region of the bladder, with excruciating pain *whenever an attempt* was made to pass the urine; great tenderness upon pressure of the abdomen; pulse quick, hard, and full; tongue dry; great thirst, and many *other symptoms* of excessive inflammatory action. *A free abstraction* of blood, both general and local, with oleaginous purgatives, enemas, warm fomentations, and a strict adherence to the antiphlogistic regimen, soon subdued *these violent* symptoms, and, on the third day, the *urine passed freely through* the *orifice* in the thigh, and continued *so to do* for many weeks; during this time, bloody urine was occasionally passed by the urethra, and frequently a considerable quantity of mucus; there was also a great sympathetic swelling of the glands in the groin. The wound at length became partially healed, *and the symptoms of stone* in the bladder were very much aggravated. I was particularly anxious at this time to introduce a sound; but neither the parents nor the patient would consent, and at length the wound entirely healed, and the swelling in the groin gradually disappeared. I then succeeded in introducing the sound, and immediately detected some foreign body in the bladder. Soon afterwards I determined upon performing the lateral operation of lithotomy, which I did on the 23rd of June, in the usual manner, with the gorget, and extracted the marble without difficulty, considerably increased in size, from a deposition of calculous matter adhering firmly to it. Not a single unfavourable symptom resulted from the operation, and in a fortnight the boy was enabled to get about. He now enjoys perfect health.

Wolverhampton,
September 15th, 1829.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8075 births and 4149 deaths were registered during the week ending Sept. 21st. The annual rate of mortality, which had been equal to 12·3 per 1000 in each of the two preceding weeks, increased to 13·5 per 1000 in the week under notice. During the first 12 weeks of the current quarter the death-rate has averaged 12·2 per 1000, the rate in London during the same period being 12·0 per 1000. The lowest death-rates in the 76 towns last week were 5·9 in Tottenham, 6·3 in Willesden, 6·6 in Halifax, and 7·0 in Hornsey; the highest rates were 19·1 in Sheffield, 19·4 in Liverpool, 20·6 in Burnley, 22·3 in Warrington, and 23·3 in Bootle. The 4149 deaths in the 76 towns last week were 356 in excess of the number in the preceding week, and included 630 which were referred to the principal epidemic diseases, against numbers increasing from 362 to 485 in the seven preceding weeks; of these 630 deaths 397 resulted from diarrhœa, 90 from whooping-cough, 49 from diphtheria, 43 from measles, 31 from scarlet fever, and 20 from "fever" (principally enteric), but not any from small-pox. No death from any of these

Bruxelles, who took a prominent part in the Congress, pointed out that in some countries, and especially in Belgium, the question of compulsory education was a "question politique irritante," and he suggested that the words "instruction le plus largement généralisée" should be inserted in the motion in lieu of the words "instruction obligatoire." This suggestion was strenuously opposed by the great majority of the members present and after a vigorous debate the decision on the question was remitted to the full meeting of the Congress in the afternoon. At this meeting Dr. WINOCOUROFF insisted on his motion being put in its original form, and his remarks roused so much enthusiasm that the PRESIDENT declared his motion to be adopted by the meeting.

An International Union.

The most important outcome of the Congress is the formation of the "International Union for the Protection of Infant Life." This organisation, which will probably play an important part in the movement for the prevention of infant mortality, has elected Dr. Escherich of Vienna as its president, and the secretary is Dr. Eugene Lust of Brussels. The Union, which has its permanent bureau in Brussels, is controlled by a committee of 50 members, including the following representatives from Great Britain:—Councillor W. F. Anderson of Glasgow, Alderman Broadbent and Dr. Moore of Huddersfield, and Dr. G. F. McCleary of Hampstead.

The next meeting of the Congress will be held in 1910 in Berlin.

THE INTERNATIONAL CONGRESS OF PSYCHIATRY.

(FROM OUR OWN CORRESPONDENT.)

(*Concluded from p. 862.*)

SECTION II.—PSYCHOLOGY.

THE section devoted to Psychology met under the presidency of Dr. G. HEYMANS, professor of philosophy at Groningen, when a few members of the Congress "in thoughts more elevate, and reasoned high" debated such subjects as the difference between apprehension and conception, the oscillations of attention, the association of object conceptions, the classification of character, the mental growth of children, and the biographical methods of psychology.

Dr. PAUL SOLLIER criticised

The Theory of the Emotions

advocated by James and Lange. These philosophers could not help seeing that the beginning of an emotion, say that of fear, was an intellectual anticipation of danger, and this is accompanied by various changes in the functions of the organism. It was pointed out as far back as 1859 by Bain in his book on "The Emotions and the Will" that "the whole brain, with all its connexions in the general framework of the body, is concurrent and participant in a state of mental emotion; and in proportion as the different parts of this extensive machinery can be diverted in other ways the emotion fails to arise or is liable to be suppressed." The difference between Dr. Sollier and James and Lange mainly is that the former seeks to circumscribe the significance of the diffused wave of nervous energy attending an emotion, whereas the latter regarding the cerebro-spinal axis and the sympathetic as one mechanism consider that the change in the whole body is an integral part of the emotion. Dr. Sollier regards the emotion as an affection of the cerebral cortex; the wave of energy which spreads through the nerves to the viscera and capillaries he considers rather to be an epi-phenomenon. He supports this view by some arguments drawn from psychological analyses and experiments on animals, but especially by a reference to pathological cases in which there is a rupture of the means of communication from the brain owing to injuries of the spinal cord below the medulla oblongata, in which Dr. Sollier tells us the emotion appears as intense as in ordinary cases. Before accepting the correctness of this statement, which would be a fatal objection to James's theory, one would like to consider the cases, nor can it quite readily be admitted that emotions at their outset are confined to the cortex cerebri, since the great mass of the white matter has surely something to do. Dr. Sollier concludes by observing that the mental representations and the modifications in the organism occur simultaneously. Emotion is really constituted by the sentiment of the diffusion of the discharge of cerebral energy along with the intense activity of the brain.

The Sthénomètre.

Dr. P. JOIRE, President de la Société Universelle d'Études Psychiques, showed to Section II. his Sthénomètre, by which he claims to be able to demonstrate the presence of a force emanating from the nervous system and of measuring its power. This emanation, he said, appears to be the same as the exteriorised force of the mediums, hitherto so difficult to demonstrate and to study. The index needle shows that it is modified in diseases of the nervous system, suffering a diminution in intensity in proportion to the nervous depression of the subject.

SECTION III.—THE CARE AND NURSING OF THE INSANE.

In this section Dr. VAN DEVENTER detailed what had been already done in Holland for the insane and laid down some proposals for

The Education, Rights, and Duties of the Attendant Attached to Hospitals for Mental Diseases.

He observed that a good staff of attendants is the knot of the question and if his proposals are adopted the duties of the superintendent will be made easy. Before entering on his work the attendant should go through a preparatory course of instruction, comprising domestic economy, cooking, household work for women, some notions about nature, teaching, especially in relation to singing, and conversation. It would be desirable that the men should know some trade which might be utilised in the asylum. In the hospital for the insane there should be a graded professional school of instruction conducted by the medical superintendent. The course should occupy three years, with yearly examinations, at the end of which a diploma may be aspired to. The attendant should be insured against accidents and bad health and an old age pension accorded.

In a report by Dr. W. P. RUYSCH the same proposals were maintained with philosophical simplicity. No one should be called upon to assume the functions of an attendant for the insane who cannot give proofs of civilisation, intelligence, capacity, and devotion, and it is desirable that such attendants should have attended with success as interne pupils in a special school. He remarked that their emoluments should be proportional with the importance and the length of their services Here, I may remark, comes in the difficulty of the undertaking. It is possible that these fine qualities may be commoner in Holland than in Great Britain, but human nature is something the same everywhere. The class of men who apply for employment at the asylums in these islands and the pay and maintenance which are allowed to them will need to be improved greatly before the candidates will appear who will come with proofs of the fine moral qualities and accomplishments desired. The vicissitudes of life and a willingness to engage in a good work sometimes bring women of a superior class to apply for employment as nurses to asylums. Few of these women have received any special training, although they often bring the capacity, moral and intellectual, of quickly learning their duties. There is a danger that by too trying examinations and by asking a long period of probation for a formal certificate forbidding barriers may be erected against good applicants.

Dr. van Deventer was followed by Dr. G. E. SHUTTLEWORTH (London) who detailed what had been done by the Asylum Workers' Association in England for the education and welfare of attendants on the insane.

Feeble minded Children in Italy.

Professor FERRARI (Bologna) gave an interesting account of what has been done for feeble-minded children in Italy. They were subjected to training under medical superintendence. In the discussion following Professor Ferrari's paper Dr. ALT (Uchtspringen, Saxony) made some observations upon the treatment of the feeble-minded in Saxony.

The Family Treatment of the Insane.

Much time was taken up by lengthy papers, the substance of which was repeated at a special conference, in praise of what is styled "the 'family' treatment of the insane."

Dr. MARIE (Villejuif) recommended *l'assistance famili e* that it has now resolved itself into a discussion which can have little interest for your readers.

I am, Sirs, yours faithfully,

Glasgow, Sept. 9th, 1907. SAMUEL SLOAN.

A CASE OF SELF-INDUCED (?) ABORTION.

To the Editors of THE LANCET.

SIRS,—In Dr. A. B. M. Thomson's short paper on the above subject in your issue of Sept. 7th he says, "The question which arose for decision was whether this was in reality a case of self-induced abortion. Is it possible for a woman to introduce into her uterus, without causing injury to the vaginal walls or to the os, a straight rigid rod four inches in length?" It may interest him and some of your other readers to hear of a remarkable case in point. Some years ago, I think it was in the "seventies," I had a patient under my care who confessed to me, and I had no reason to doubt her word, that she had brought on abortion on herself sixty-five (65) times! The instrument she used was a bone knitting-needle. She used to squat down and, finding the os, pass the knitting-needle into the uterus. She was so regular in her periods that she knew at once when she had conceived and immediately proceeded to operate; and though on several occasions she had rather severe hæmorrhage, yet, as far as I remember, she was never in any serious danger; a rather remarkable result in those pre-aseptic days.—I am, Sirs, yours faithfully,

[illegible]-street, W., Sept. 12th, 1907. HEYWOOD SMITH.

RESULTS IN APPENDICITIS TREATED BY THE IMMEDIATE AND COMPLETE OPERATION.

To the Editors of THE LANCET.

SIRS,—The controversy whether it is better to operate within the first few hours of the onset of appendicitis or whether it is better to wait until there is some definite call for operation has gone on for many years.

Mr. W. G. Spencer is to be congratulated upon having a consecutive series of 100 cases of appendicitis (published in THE LANCET of Sept. 14th, p. 770) with but seven deaths, or four if we exclude the three cases who had other lesions as well. But if we accept the title of his paper and his concluding paragraph—viz., "that it has been possible to diagnose and to operate on 100 cases of appendicitis, with a loss, when the appendicitis was the sole disease, of only four, a result which removes the various objections that have been raised to the method"—it will be seen that those of us who have an open mind upon this question can derive but little instruction upon this important point. If it is true that the immediate and complete operation is responsible for so low a death-rate as 4 (or 7) per 100 cases, then every right-thinking surgeon should adopt the immediate treatment. But let us look more closely at these 100 cases.

Class 1.—37 cases; no deaths. Admirable. But these are defined as "cases in the interval between the attacks, or early acute and subacute cases." How many of these were "interval" cases is not stated, but it seriously reduces the 100 cases submitted to "immediate" treatment, unless "immediate" only means "as soon as they came under Mr. Spencer's care." No good surgeon in these days expects otherwise than to obtain equally satisfactory figures from this type of case whether they are done immediately or in a week or two. Then "subacute" is a term open to misunderstanding. Does it mean that they were recognised as very mild cases, or were they recovering from acute attacks, and if the latter, how "immediate" was their treatment? Mr. Spencer says, "*some* of these cases would have recovered without operation, *others* would have become rapidly worse had the operation been delayed"; but as he dispensed with drainage in all, he evidently did not think so badly of them.

Class 2.—These are labelled gangrenous and perforating appendicitis and *subacute appendicitis*. 31 cases; four deaths. All will agree that the sooner gangrenous and perforating cases are operated upon the better, but why put subacute cases into this class? How many of these were subacute, and, if so, how early were they operated upon?

Class 3.—Cases of suppurating appendicitis treated by removal of the appendix and drainage. Again comes the question as to how elastic a term is the " paper. I suppose a good many of these cases had an abscess for several days; at any rate, I frequently get cases at the Children's Hospital who are brought up from seven to ten days after the onset of the illness with large localised abscesses. These are opened at once, but it is hardly looked upon in the sense of the "immediate" operation. The removal of the appendix at this stage must certainly add to the danger of the operation, as it risks infection of the peritoneal cavity when the patient's tissues have, after much trouble, walled it off into a position of safety. I know authorities differ on this point but I have never regretted not removing the appendix in opening a localised abscess.

Class 4.—As in Class 3, there is no guide to the time of the various operations, still, as they were suppurating cases, they are hardly likely to have been very early ones.

I am not cavilling at the early operation done within a few hours of the onset of appendicitis, but I do think that this series of 100 cases with four (or seven) deaths is gravely fallacious as a proof of the benefits of early operative treatment when interval cases are included, and when we get no guide in the majority of the cases as to how soon after the onset the operation was performed. Instead of the death-rate being reduced to 4 per 100 as a result of the immediate operation it must be—well, perhaps Mr. Spencer will give us a more accurately analysed list.

I am, Sirs, yours faithfully,

Upper Wimpole-street, W., Sept. 14th, 1907. JOSEPH CUNNING.

ERYSIPELAS (?) IN A YOUNG CHILD.

To the Editors of THE LANCET.

SIRS,—The following note may be of interest, as I can find but few recorded cases of a similar nature.

The patient was a little girl, aged five years, who was brought to my house about a week ago with a sharply-defined bright-red patch on the right cheek. I told her mother that had it not been for the child's age, when such an affection was very unusual, I should certainly have diagnosed the case as commencing erysipelas. The child's skin was hot and dry, the temperature was 101·4° F., and there was distinct albuminuria. I prescribed a simple febrifuge and asked that I might be informed if there should be any further developments. Two days later I was asked to see the patient at her own home, where I found her presenting all the appearances of a typical case of facial erysipelas. The face was swollen to the extent of being unrecognisable: there was marked œdema of the eyelids; and there was a well-marked line of demarcation between the erysipelatous and the healthy skin.

Since then the case has run an uneventful course, the redness becoming daily less marked and the temperature gradually falling from 102·8° to within a point or two of normal. Treatment has been on the usual lines. There was no history of any injury, there was no affection of the ear or throat, and the child's teeth were in good order. Her mother told me that when I first saw her she had just returned from a country holiday but she could not think of any possible exposure to infection. The drains of the house in which they stayed were, so far as she could tell, satisfactory.

I shall be glad if any of your readers who have met with similar cases at such an early age will favour me with a few facts concerning them, and with suggestions as to their probable cause.—I am, Sirs, yours faithfully,

T. R. HENDERSON, M.B., C.M. Edin.

Bedford Hill, Balham, S.W., Sept. 15th, 1907.

ARTHROPATHY IN RÖTHELN.

To the Editors of THE LANCET.

SIRS,—While the nature of rheumatoid arthritis is under discussion I should like to place on record the occurrence of an arthropathy during the course of rötheln. The patient was a young man, aged 24 years, who, after a few days of sore-throat, stiff neck, malaise, and moderate fever, developed a rash having the distribution and appearance of German measles and accompanied by an enlargement of superficial glands, notably those of the neck. Before the exanthem had faded the patient began to complain of stiffness and tenderness in the knees and ankles, and soon all the inter-phalangeal joints of the fingers presented the spindle-like swelling commonly seen in rheumatoid arthritis. There was no exacerbation of

er

he

et le travail agricole for quiet chronic lunatics and for convalescents. The idea of colonies around the asylum was favoured. Harmless patients and epileptics might be boarded at greater distances.

Dr. PEETERS (Gheel) expressed the opinion that in what he called the "closed" asylums (*asiles fermés*) there was a considerable danger of the patients falling into dementia owing to the lack of amusement and employment, and he even considered that Gheel was better for acute cases.

The Sanatorium Treatment of Insanity.

A paper on the Sanatorium Treatment of Active Insanity by Rest in Bed in the Open Air by Dr. C. C. EASTERBROOK (Ayr) was read by Dr. J. H. MACDONALD (Paisley). The following passage thus sums up his results: "Comparing then the general therapeutical effects in active insanity of outdoor exercise, indoor rest, and outdoor rest, I find that outdoor exercise benefits primarily the physical condition but may retard the mental improvement; that indoor rest benefits primarily the mental condition but may retard the physical improvement; and that outdoor rest benefits from the first both the mental and the physical condition. Outdoor rest thus from the outset promotes both mental and physical improvement, and so retards neither; further, it avoids the risk of undue exhaustion which attaches to the method of exercise; and lastly, it obviates the evils of bodily inactivity and sluggish metabolism which attach to prolonged indoor rest."

Dr. REUTERGHEM (Amsterdam) defended the treatment of hypnotic suggestion against the objections of Déjerine and Dubois; in this he was vigorously supported by Dr. C. LLOYD TUCKEY (London).

Dr. W. W. IRELAND (Musselburgh) read a paper upon the Increase of Diseases of the Nervous System and of Insanity, in which he argued that these derangements were found to be increasing beyond the general increase of the population in every country which furnished statistics, except Norway. The paper is published in full at p. 892 of our present issue.

EXCURSIONS AND PLEASURE VISITS.

The Congress was finished on Sept. 7th by an excursion to Leyden, the Hague, and the asylum at Endergeest. This is situated within large grounds with high trees; the rooms are light and airy, the wooden beds are clean and comfortable, although the furniture is scanty compared with what is seen in British asylums. The equipment of the laboratory is admirable. The excursion finished by a visit to Schevening, the fashionable watering-place of Holland. In the Kursaal 150 guests sat down to an excellent dinner. Appropriate speeches were made by the presidents and other dignitaries. The foreign delegates returned thanks for the courtesy with which they had been treated. After a concert in the large music hall and a display of fireworks the company got back to Amsterdam about midnight, having been away since half-past nine in the morning.

The amusements provided during the week by the hospitable care of the Amsterdamers formed an attractive and improving feature of the Congress. These recreations, besides the opening ceremony already mentioned, comprised a *soirée* by Dr. and Mrs. van Deventer in some beautiful rooms in the Keisergracht, a reception by the burgomaster, and an entertainment by the students' club. There was an excellent entertainment in the Leidisch Plein Theatre where Dutch national songs were sung by a chorus of 20 girls dressed in white and some male vocalists. The Dutch excel in singing in chorus. In the intervals *tableaux vivants* were exhibited reproducing some Dutch paintings representing medical subjects, which included Rembrandt's picture of Professor Tulp giving an anatomical lecture with a dead body in the foreground.

On Sept. 4th there was a pleasant boating excursion to Zaandam where was seen the wooden hut in which Peter the Great lived when he came to Holland to learn shipbuilding.

The visitors left Amsterdam grateful for the unaffected kindness and courtesy with which all had been treated. Thanks are especially due to Dr. van Deventer, Dr. van Wayenburg, and Dr. Londen, to whose good offices so much of the success of the Congress was due. It was gratifying to have so favourable an opportunity of witnessing the energy and intellectual capacity of the Dutch people who inhabit a small country which they have rescued from the sea but which has a history inferior to none in illustrious deeds. Men like Deventer, Jelgersma, and Wertheim Salomonson are worthy successors to Boerhaave, Swammerdam, and Schroeder van der Kolk.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Black Smoke Problem.

AT Preston yesterday a firm of cotton manufacturers was summoned for failing to comply with a notice to abate a smoke nuisance. Mr. H O. Pilkington, the medical officer of health, said that the evidence proved a nuisance. For the firm it was stated that they were trying to abate the nuisance and had spent £85 on one chimney. The further expression of opinion was hazarded that "there was nothing yet known that would cure the black smoke nuisance." If this were the last word to be said on the matter the dwellers in our towns would have a hopeless future. As the two magistrates on the bench could not agree the chairman thought that it would be better if the case were heard before a fuller bench. This hopelessness as to getting rid of the smoke nuisance did not show itself during the discussion on the subject at the recent sanitary conference at Llandudno. Those who suffer do not need the eloquent indictment of Sir William Richmond to strengthen their feelings on the subject, though the destructive effects on our public buildings as set forth raise the question above the personal sphere. But Mr. Nicholson, a sanitary inspector from Sheffield, showed how much can be done in the way of prevention, without expensive appliances, by careful and intelligent stoking. But the care and the intelligence are not always exercised. These qualities have sometimes been quickened by rewards for the least production of smoke and great improvement has been the result. Mr. Nicholson summed up the matter briefly when he said: "It was quite possible to prevent the emission of black smoke without special appliances, provided there was ample boiler power, reasonable draught, fair fuel, and intelligent stoking." Mr. Rooke of Manchester showed the unfortunate position of the town in being surrounded by large and important manufacturing towns, so that whichever way the wind blew the city got some of the smoke from its neighbours. This is especially hard in the case of Manchester, as it heads the list for its work in regard to the suppression of the smoke nuisance. As Mr. Rooke said, if the districts round Manchester would only carry out the law to the same extent Manchester would have a much purer atmosphere than it has to-day. It is interesting to note that at the recent meetings of the Chambers of Commerce, where it was moved from Manchester that it was desirable to minimise the emission from manufactories of dense volumes of black smoke, "the resolution met with considerable opposition from the representatives of manufacturing centres." The proposition was, however, carried. It is a fact to be lamented that there are still people who will vote for the continuance of black smoke and a polluted atmosphere.

The Infirmary Site.

As to the present site of the Royal Infirmary, the question as regards the corporation most frequently asked is, What will they do with it? Some want the present building pulled down and a free library and art gallery "worthy of the city" put in its place. Others think that the present buildings might very well be altered and adapted so as to serve the same purpose. The corporation, in presence of this clash of opinions, has decided to obtain "the opinion of an eminent architect, absolutely free from local bias" on the question as to whether it is possible or desirable to adapt the infirmary buildings for the purposes named. It has, therefore, asked Mr. T. E Collcutt, president of the Royal Institute of British Architects, to report as to their adaptability to the purposes of a reference library, art gallery, and municipal offices.

Nursing at the Macclesfield Workhouse.

The Macclesfield board of guardians discussed the nursing arrangements at the union infirmary on Sept. 17th, and it was proposed that the medical officer to the workhouse should report to the board on the organisation of the nursing staff and on the many changes that take place and the engagement of temporary nurses. One of the medical guardians thought that the organisation was at fault and he objected to the course adopted by the board of advertising

Highlanders): Surgeon-Major D. H. Kyle resigns his commission (dated August 5th, 1907).

DEATHS IN THE SERVICES.

Fleet-Surgeon James Thomas William Stenteford Kellard, R.N. (retired), suddenly, at Waterlooville, Hampshire, on Sept. 16th, in his 55th year. He entered the Royal Navy as assistant surgeon in 1876, and became *fleet-surgeon* in 1897. In November of the same year he retired, and had since then resided at Southsea.

Correspondence.

"Audi alteram partem."

THE MEDICAL REGISTER.

To the Editors of THE LANCET.

SIRS,—May I ask you in the interests of the profession to draw attention once more to the importance of notifying to this office changes of address for insertion in the Medical *Register*; *omission to do this* sometimes leads to a temporary removal of the name, with its consequent inconvenience. The Medical Register is the official publication and should not be confused with any of the medical directories which issue circulars annually. I might also add that if the signatures are written clearly and the full names, or at least the full initials, are given, much trouble will be saved.

Yours faithfully,
H. E. ALLEN,
299, Oxford-street, London, W., Sept. 23rd, 1907. Registrar.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—I am sorry that Dr. J. C. Bowie in his letter in THE LANCET of Sept. 7th, p. 732, should have thought it necessary to attribute to me a desire for approbation. I had believed when writing my last letter that it was truth more than triumph I was seeking. I fear that Dr. Bowie in his reply leaves the matters in dispute between us very much where they were. He continues to state what ought to be, not what he has found to be, the case. I desire criticism of what I have stated to be facts. I had believed that my paper teemed with these, yet no attempt has been made to controvert even one of them by actual experiment.

Dr. Bowie makes much of the question of wattage in the output. I made no objection to this, only saying that wattage, as he interprets it, was not required *as well as* voltage and ampèrage. His wattage theory, however, is absolutely irrelevant to a discussion on my contribution to your columns. I have stated that the dose given has been so and so—400 milliampères or 500 as the case may be. This milliampere meter reading is a *thermic fact*, as I have explained, being measured by a hot wire galvanometer. Dr. Bowie seems to forget, however, that in alternating current phenomena wattage is not got by simply multiplying voltage by ampèrage, as in continuous current; and this is the answer to his argument based on wattage of input and wattage of output. As I have said, we cannot speak of wattage in high-frequency currents in the manner in which he insists on doing. As I have also before stated, it is a current in the meter but *a capacity in the body*. I have in the records of my experiments given the measure in the meter, refraining from venturing to predict what capacity this may represent in the body. His claim regarding wattage will be perfectly satisfied, however, I understand, if we suppose that what corresponds in the meter to a heat equivalent of 500 milliampères *may* represent a capacity of 16 milliampères in the body. Not only am I ready to grant that this may be so, but I am willing to go even further than this for the sake of ease of calculation and for argument's sake, though, as the lawyers say, without prejudice, and make it five milliampères in the body. This, however, it must be remembered, is *an inference only*, though an interesting one I admit, whilst the figures given in my charts still remain thermic facts which can be tested and measured by anyone. Thus the wattage as an energy affecting the body, according to Dr. Bowie's method of calculating it in connexion with high-frequency currents, becomes 400—namely, 80,000 volts multiplied by 0·005 ampère, though Dr. Bowie has all along been willing to give me 1250 watts. The facts recorded in my charts, however, remain unchanged and my *thesis remains practically unchallenged. For 500 milliampères in the meter read five milliampères as the ampèrage capacity in the body; for, say, 400 milliampères in the meter* as the quantity running off to zero from the axilla read four milliampères as the actual capacity in ampèrage at the axilla; for 250 milliampères as passing to zero from the foot read 2·5 milliampères as the actual capacity in ampèrage there. What I wish and maintain that I have established *remains unaffected—namely, that* the fall in the current to zero and the fall of potential from the point of entrance of the current to any part of the body selected for measurement proceed practically *pari passu*. I have endeavoured to explain why it is not absolutely so, as I thought it should be. That more than a small percentage of the current passing through the meter is the ampèrage capacity in the body I feel sure; but this also being a mere inference we need not occupy our time discussing it, since it has no bearing on the question of the validity of my statements regarding certain physical facts observed by me. I am prepared neither to accept nor to reject this hypothesis. I have in my original article purposely made no assertion as to the relation of the current in the meter to the capacity in the body, limiting myself mainly to statements as to what I actually found as facts. Some recent experiments made by me warrant me, however, in believing that the heat equivalent in milliampères of the effective electric energy surging in the body during auto-condensation, when the meter registers 500 milliampères, is to be measured not by units but by hundreds. If Dr. Bowie tries the experiments I have described and does not get the same results then myself and others must repeat the experiments that thus we may get at the truth. If authorities are anathema in Dr. Bowie's eyes he must give us more evidence in support of his own claims as a new authority than his mere *ipse dixit*. Far from invoking authority myself, however, all my investigations were meant for tests of past authorities, as I make plain at the beginning of my paper. Regarding many points Dr. Bowie brings forward no evidence of the correctness of his beliefs. He simply contents himself with repeating them.

If, then, his wattage theory can be made to mean nothing and his potential theory remains unproved, what is left in dispute between us? Only some, I have no doubt interesting, experiments with a vacuum tube for the production of ultra-violet rays. I should very much like to see this apparatus at some future date, but it has nothing to do with my contribution on the physiological effects of high-frequency currents. Since he tells us that he passes through this tube a current of 250 milliampères at a pressure of 30,000 volts, however, it would be interesting to know what the wattage of the input is in order to get an output wattage of 7500, as he calculates wattage in alternating currents.

Dr. Bowie has not explained how he is to get five ampères through the body out of 80 volts. My objection is not to the 400 watts but to the five ampères at a voltage of 80. The question as to the relative physiological effects of a high voltage and a small current as against a comparatively low voltage and a relatively high current would be an interesting investigation, but it has absolutely nothing to do with the original subject of my communication and is, *therefore*, in no sense a criticism of it. What Dr. Bowie says regarding my failure to attach importance to time, quantity, voltage, &c., is apt to mislead your readers. If my charts are referred to it will be seen that time and quantity are practically always given and my results are based on these data. Where the quantity and time have been omitted it is an unintentional omission. I have full details of all the cases in my notes and can let Dr. Bowie or anyone interested have them.

When Dr. Bowie has had time to test my experiments I shall be glad to hear from him either privately or through the medium of your columns. My facts—not myself—are "on approbation," that is, they are waiting to be probed. What is wanted is real practical criticism. Unless Dr. Bowie is prepared to give this practical criticism a continuance of this correspondence is, in my opinion, useless, wasteful alike of my time and of valuable space in your columns, seeing for a nurse with certain qualifications and then appointing someone who did not possess them. Some candidates afterwards appeared but none had the necessary qualifications; it was agreed to readvertise the vacancies.

Salford Royal Hospital.

It has long been felt that the Salford Royal Hospital required extension. It is the only general hospital in Salford, with its population of 235,000 to 240,000 people, with a very large proportion of the working classes, and it is believed that when the Manchester Royal Infirmary leaves Piccadilly for Oxford-road the strain on its resources will be materially increased. At present there are 135 beds and it is proposed to have 200, while more accommodation is required for the nurses and staff and for domestic offices. Adjoining land will have to be purchased and the total cost is estimated at £70,000. Up to the present £27,081 have been received or promised, so that £42,000 have still to be raised. During the past three years the number of out- and home-patients has averaged nearly 20,000 per annum and there has been a considerable increase in the number of in-patients and accident cases. Unfortunately, for the last ten years or so the expenditure has exceeded the income by about £1300 a year and capital funds have been trenched on to meet the recurring deficits. But the average cost per occupied bed of about £43 per annum compares favourably with that of other similar institutions. The authorities of the hospital think that they have a strong claim on the generosity of the public, to which they make a special appeal.

Poisoning by Carbolic Acid.

Carbolic acid is such a familiar domestic article that its being a poison is liable to be forgotten, even though it is, strangely enough, a favourite agent of the suicide and causes more accidental deaths than perhaps any other poison. An inquest held the other day illustrates the carelessness of many working-class people with regard to carbolic acid. A child, three years old, the son of a miner of Failsworth, asked his six-year-old sister for a drink. She took a large bottle off the chimney-piece, thinking it was herb beer, and gave it to the boy. He drank some of the contents and screamed. He was taken to the Royal Infirmary but did not recover from the shock and died there. The verdict was "Death by misadventure" and the jury added that the bottle ought not to have been left within reach of the children. Carbolic acid is, of course, a very useful thing but the cause of a considerable needless loss of life, and the regulations as to its sale should be as stringent as in the case of any other poison. It is unfortunate that several other equally useful but much less poisonous preparations are not more frequently used in its place.

Fatal Homely Remedy.

AN unusual cause of death was investigated at Blackburn 10 or 11 days ago. A woman, aged 60 years, had made a saucer hot and put it under her clothes over her heart as she had suffered from pains in the chest. While crossing the street she fell and was carried home unconscious. It was found that the saucer was broken and that three large pieces had penetrated the chest wall, "medical skill being required for their extraction." She died almost immediately.

Sept. 24th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Workhouse Infirmary.

SINCE the extension of the city boundaries there have been in Bristol three workhouses—at Eastville, Stapleton, and Southmead. At Eastville there are about 200 sick persons housed in temporary wood and iron buildings under conditions which cause some anxiety to those concerned with the administration of the institutions. Upon many occasions during the past few years the Local Government Board has urged upon the board of guardians the desirability of doing away with these structures and providing better and safer accommodation. Various schemes have been proposed and have arrived at a stage when it appeared likely that they would be adopted, but upon one pretext or another, usually that of expense, they have been abandoned. The latest project was considered by the board of guardians on Sept. 20th. It involved the removal of all the wooden buildings at Eastville and the erection of a double pavilion of a permanent character to accommodate 192 beds at a cost of £13,000. The committee which had the matter under consideration recommended that any alteration of accommodation should be so arranged as to enable a complete system of classification to be adopted by utilising the Stapleton buildings for the imbeciles and epileptics, those at Southmead for the aged and able-bodied, and those at Eastville for the sick. This proposal would entail extensions at each of the three institutions, but it appears to be the most economical and at the same time satisfactory scheme which has yet been considered. It is to be regretted that the recommendation of the committee did not receive the support of a majority of the board which refused to endorse them on the plea that they lacked finality and opened out possibilities of future expense. In the end it was decided to appoint a committee to make arrangements to remove the helpless sick from the wooden buildings at Eastville. One member of the board ridiculed the suggestion that there was more danger from fire in the wooden buildings than in more permanent structures, though it is felt by those experienced in such matters that the retention of the former places a very serious responsibility upon those members of the board of guardians who are opposed to their removal.

Vaccination Fees in Herefordshire.

The fees to be paid to the public vaccinators have now been agreed upon with one exception in each of the eight Herefordshire unions. In the city of Hereford the fee has been reduced from 5*s*. to 3*s*. 6*d*. Elsewhere the only alteration has reference to a second operation performed in the same house within 24 hours. In three unions the fee in this case is to be 2*s*. 6*d*. and in one 3*s*. 6*d*., while in three others there will be no reduction. The exception indicated above is the Bromyard union where there is as cattered population living in a hilly district on the borders of Herefordshire and Worcestershire. There are three public vaccinators and it was suggested by members of the board of guardians that they should be paid a fee of 4*s*. however great the distance to be travelled. As they very properly declined to accept so inadequate a sum the Local Government Board is to be asked to fix theamount.

Housing at Ebbw Vale.

The medical officer of health of Ebbw Vale has frequently drawn attention to the need of more houses in the district and on one occasion described certain cottages as more like pigsties than anything else. The lack of houses has been taken advantage of by some landlords who have raised the rents to a considerable extent, so much so that it is stated in some instances the workmen pay as rent one-half their wages. Two years ago the urban district council decided to build 20 houses but the Local Government Board would not sanction a loan for the purpose owing to the sites selected being too far distant from the collieries. The matter is still more urgent now than it was formerly and it is hoped that more suitable sites have been secured, so that the erection of houses by the council may be begun. It is intended to have a bath-room in each house.

Madame Patti at Swansea.

Madame Adelina Patti (Baroness Cederstrom) has upon many occasions organised concerts in Cardiff, Swansea, and Brecon for charitable purposes and the local hospitals have always benefited to a considerable extent. About £650 will be handed over to the Swansea Hospital as the result of the latest concert given by Madame Patti on Sept. 19th. This was the ninth occasion upon which she has thus helped the funds of the hospital.

Sept. 24th.

SCOTLAND.

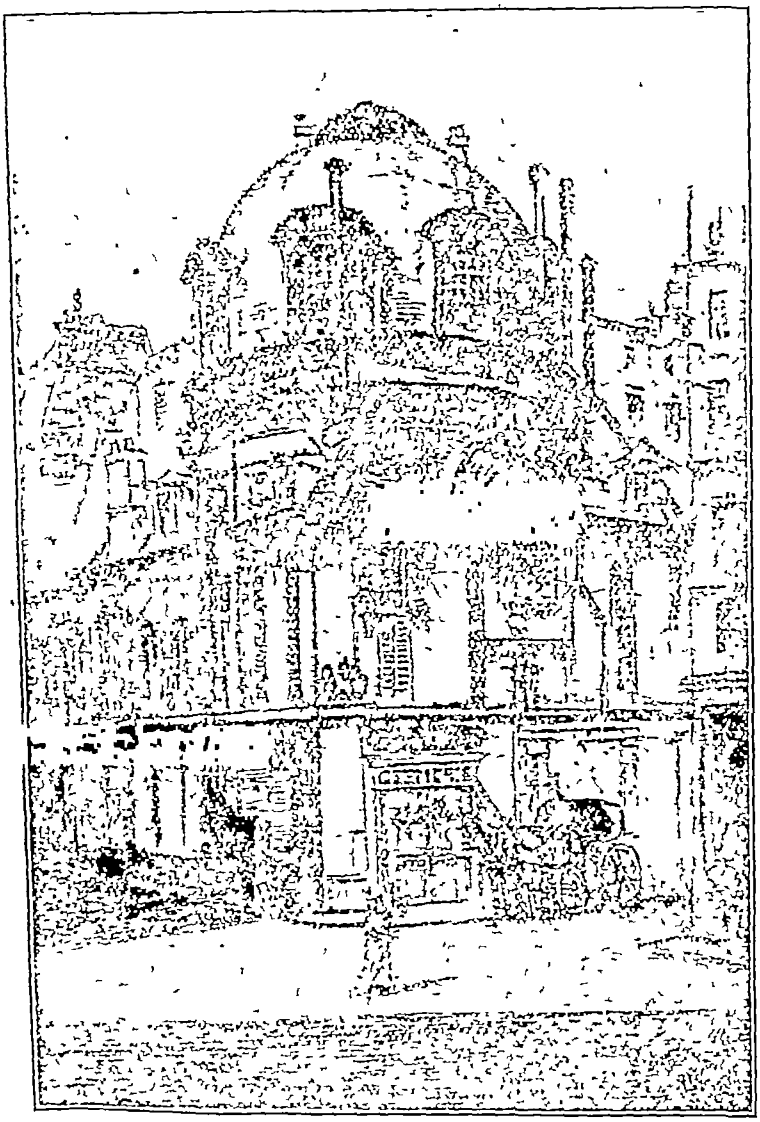
(FROM OUR OWN CORRESPONDENTS.)

Memorial to the late Dr. James Wilson of Govan.

THE fountain which has been erected to the memory of Dr. James Wilson, who was for 21 years a medical practitioner in Govan, was unveiled last week. The chairman of the committee presided and introduced Mr. Robert Duncan, M.P., who, in handing over the gift, eulogised the work of Dr. Wilson. Provost Anthony, one behalf of the town council, accepted the gift.

Portrait of Professor J. G. McKendrick.

In the early part of the year a movement was initiated oath of the physicians was taken kneeling before the altar of St. Denis in Notre Dame (the spot now occupied by a monument dedicated to Archbishop Affre). In the old chapel of the school there was a painting of St. Luke, and on his fête day, a special mass was celebrated and chanted by the physians, who were at the same time monks or occasionally canons of Notre Dame.



The Old School of Medicine of Paris.

The accompanying etching by Miss Katherine Kimball was made in 1904 for reproduction in Okey's "Paris." Since then the building has been to a great extent demolished, and has, I believe, been handed over to the Association des Etudiants de Médecine. The etching shows Winslow's cupola. The building in its present state cannot stand for any time and must be rebuilt. The original amphitheatre was constructed of wood and open at the side—rather a contrast to our modern well equipped and comfortable anatomical rooms and theatres. In those days mules were ridden by the physicians, so posts were placed at the sides of the doors of the schools to assist them in alighting.

MEDICINE AND THE LAW.

Trial for Murder and Concealment of Birth in Essex.

At the recent assizes at Chelmsford two women, a domestic servant, aged 21 years, and her grandmother, aged 74 years, were indicted for the murder of the infant child of the former. The charge of murder against the younger prisoner was withdrawn by the counsel for the Treasury before the trial but was proceeded with against the elder one, who was eventually acquitted. Both prisoners were found guilty of concealment of birth. The evidence showed that undoubtedly the younger prisoner, Emily Campion, had been delivered of an illegitimate child at the house of her grandmother, Maria Webb, and that the latter had given the dead body to a male relative who had buried it in his garden, preserving the secret as was not unnatural. In these circumstances it will easily be understood that there was no evidence of the commission of the crime of murder except the medical evidence founded upon post-mortem examination and upon statements made by the prisoners. The concealment of the birth, the manner in which the body was disposed of, and much of what was said by the prisoners in the course of inquiries, apparently of a somewhat inquisitorial nature, on the part of the police were equally consistent with the child having been born alive or dead. On behalf of the Treasury the medical evidence was given by Mr. Henry J. Price and Mr. A. E. Lyster. The former president-elect, Dr. J. Dunlop (Bradford), Dr. A. Campbell (Dundee), Dr. J. Walton Browne (Belfast), Mr. D. I. McVeagh (Coventry), Dr. T. F. Higgs (Dudley), Mr. W. A. Berridge (Redhill), Dr. M. Coates (Streatham), and Dr. R. R. Giddings (Nottingham), the honorary general secretary, waited upon Mr. Buxton at St. Martin's-le-Grand on June 27th. The Postmaster-General was accompanied by Mr. Babington Smith, C.B., C.S.I., and Mr. Arthur H. Wilson, respectively the secretary and the medical officer-in-chief to the Post Office. The outcome of the interview was, we understand, most satisfactory to the deputation, Mr. Buxton, after courteously listening to the arguments advanced, coming to the following decision :—

1. That present and prospective postal medical officers over 70 years of age are, if they desire to retain their appointments, personally to bring their cases under the notice of the Postmaster-General, and in all cases where they can be shown to be still efficient he will favourably consider them for retention in their present positions.

2. That only where a postal medical officer is hopelessly inefficient and his inefficiency is such that there is no possibility of him improving will he in future be discharged without a warning, but that where a medical officer is getting slack and showing inefficiency in the opinion of the department he will be given 12 months' notice and will be reported upon again at the expiration of that time and if it should occur that he can then be reported as being efficient his services will be retained.

3. That whenever a postal medical officer is reported as being inefficient he will be given information of the nature of his inefficiency in general terms, and if any specific charge is preferred against him it will be stated. If any postal medical officer reported as inefficient considers that the charge is an unjust one he will in future be entitled to have a personal interview with the medical officer-in-chief or the second medical officer at the London head Post Office and to lay then before him any matters in explanation or extenuation of the charge.

4. That Mr. Buxton requested to be supplied by the Association of British Postal Medical Officers with a memorandum of its proposed scheme of superannuation for medical officers and promised to accord it his sympathetic consideration, adding, however, that if it converted him it would still be a matter for the Treasury to decide upon.

THE new premises of the City of London Lying-in Hospital, City-road, were formally opened on Monday last, July 1st, by H.R.H. Princess Christian in the presence of the Lord Mayor of London, Sir William Treloar, who is the president of the charity, and of a large number of the supporters of the hospital, the committee, and the staff.

Dr. Donald MacAlister, President of the General Medical Council and Principal of the University of Glasgow, has been appointed by the Crown on the governing body of the Imperial College of Science and Technology, and appears to be the only member of the medical profession nominated to serve on that body.

THE Laryngological Section of the newly constituted Royal Society of Medicine will hold its first general meeting at 20, Hanover-square, London, W., on Tuesday, July 9th, at 5 P.M., for the adoption of rules, the election of a council, and the transaction of other necessary business.

THE annual Congress of the Royal Institute of Public Health was opened on Saturday evening, June 29th, at Douglas, Isle of Man, by Lord Raglan, the President of the Institute for the year and the Lieutenant-Governor of the island.

KING'S COLLEGE HOSPITAL.—In aid of the fund of King's College Hospital a festival dinner was held at the Hotel Cecil on June 28th. Lord Methuen presided, and in proposing "Success to King's College Hospital" he traced the history of the institution and said that the removal of the hospital to South London would cost £300,000. Mr. W. F. D. Smith, M.P., had given 12 acres of land at a cost of £62,000. The annual expenditure of the hospital was about £22,000 and the ordinary income £16,000. He hoped the time was far distant when the hospitals of London would be placed upon the rates, and he appealed to the charitable public to prevent this. The support of medical schools was only second to the support of hospitals and the public ought to subscribe freely to this branch of hospital work. A sum of about £1400 was collected during the evening.

IMPORTANT EPOCHS IN THE HISTORY OF THE OLD SCHOOL OF MEDICINE OF PARIS.[1]

BY H. MACNAUGHTON-JONES, M.D. Q.U.I.

IN 1281 the Faculty of Medicine, desirous of having a separate building and depository for its archives, had its first installation beside the School of Arts in the rue Escholes des Escholiers. The first authentic acquisition of property occurred on May 24th, 1309. In the rue du Fouarre from the thirteenth to the fourteenth centuries the Faculties of Arts and Medicine were united. In 1369 the two faculties separated, and that of medicine obtained a house at the corner of the rue des Rats and the rue de la Bucherie. This was the cradle of the Medical School.

Dulaure, in his "History of Paris" (p. 242), says that in the School of Medicine, situated in the rue de la Bucherie, No. 15, medicine was taught in the University of Paris. But this science was very little advanced and contaminated by magical practices had no special school. In 1469 the University assembled at Notre Dame, and determined to establish a separate institution for the teaching of medicine. An old building belonging to the Carthusian nuns was secured in the rue de la Bucherie. The construction of the school building was commenced in 1477. Following the ancient custom the professors and scholars were fathers (priests), though they were called "physicians" or sometimes "doctors."

Little by little the neighbouring buildings were encroached upon and in 1608 the house which formed the corner of the rue du Fouarre[2] and the rue de la Bucherie was acquired and an anatomical amphitheatre was constructed. Gradually the Faculty increased and modified its internal installation, the outside of the buildings giving but little idea of the character of the school at this time. It was in the middle of the eighteenth century that the amphitheatre, of which we see the cupola (shown in the etching) at the corner of the rue de la Bucherie and the rue de l'Hôtel Colbert, was constructed (1742–44), and this was solemnly inaugurated on Feb. 18th, 1745, by the celebrated anatomist, Winslow, who taught here. Despite many restorations the buildings were in such a state of repair that in 1775 the Faculty was obliged to install itself in the rue St. Jean-de-Beauvais (given up by the Faculté de Droit), where it remains to the present day.

Up to the middle of the fifteenth century all the members of the different grades in the University were designated by the name of "*clerc*," which had reference to their religious character, and celibacy was imposed on the doctors of medicine as on the other members of the clergy. The University of Paris was then a great intellectual centre for the entire world, and up to 1790 the diplomas that it granted to its medical graduates entitled them to practise "*urbi et orbi*." The University, composed of four faculties, Arts, Theology, "La Faculté de Droit Civil et de Droit Canon" (still called the "Faculté des Décrets") and Medicine, had special rights over that portion of Paris situated on the left bank of the Seine. The students were mainly recruited from the bourgeois class, and their lives were intimately associated with it. "Arts" was the oldest of the faculties and medicine was probably not acknowledged until 1270.

In 1792, after the cessation of the Faculty of Medicine, the buildings of the rue de la Bucherie became national property. They were restored in 1810 and divided into many lots. In 1896, when the town of Paris took them over, the lower schools were converted into a lavatory, the amphitheatre was occupied by a wine merchant, and a billiard saloon was installed on the spot where Winslow had taught. The chapel, botanical garden, and the library had all disappeared. Referring to this demolition Dr. René Fauvelle says: "Sic transit gloria mundi." The tablets on the old building bore the inscription "Scholæ Medicorum." Corlieu in his brochure "L'Ancienne Faculté de Médecine de Paris" calls it "le berceau de notre profession."

It is interesting to note that in olden times the celebrated recognise in some appropriate manner the services to ience of Professor J. G McKendrick, who last year retired om the chair of physiology in the University of Glasgow. s part of the scheme it was decided that a portrait of Pro- sor McKendrick should be presented to the University, d Mr. J. H. Lorimer, R S A , has been commissioned to ecute this. It is expected that the formal presentation ill take place at the biennial commemoration ceremony at e University in April next. The balance of the fund will e expended on the equipment of a laboratory of experimental ychology.

---

[1] Taken from the work of Dr. René Fauvelle, "Les Etudiants en Médecine sous le Grand Roi," and Dulaure's "Histoire de Paris," and Corlieu's "L'Ancienne Faculté de Médecine."

[2] Now the rue de l'Hôtel Colbert since 1828. The rue de Fouarre has been suppressed in part by the extension of the rue Lagrange to the Quay.

Retirement of Dr. James Rutherford.

Dr. James Rutherford, the medical superintendent of the richton Royal Institution, Dumfries, has tendered his signation on account of the state of his health. In the years during which Dr. Rutherford has been at the head the institution it has been greatly developed on the most odern lines. The asylum is endowed and receives private ying patients to the number of about 500. It also ovides in separate buildings for the mentally afflicted who e chargeable to the parish councils of Dumfriesshire and lloway.

Physics Laboratory for University College, Dundee.

Plans have now been approved for the Carnegie Physics boratory which is to be erected in connexion with niversity College, Dundee, and building operations will be mmenced immediately. The building will consist of two oreys with basement and attics and will be fitted up ter the most modern methods.

Annual Report of the Campbell Hospital, Portsoy.

The annual report by the joint board of the Campbell ospital has just been issued. During the past year the spital has been very fully occupied. On May 15th, 1906, ere were three patients in the hospital and since then there ve been admitted and treated 53 patients. Of these 56 tients 54 were discharged during the year cured and one ed, leaving in hospital on May 15th, 1907, one patient who s since been discharged cured. Of the 56 patients 26 were ffering from typhoid fever, 27 from scarlet fever, and three om diphtheria. The patients were admitted from the areas Banff, Macduff, Portsoy, and Cullen local authorities. here were no "return" cases and no cases of cross infection. ring the year the hospital has had to cope with a rious outbreak of typhoid fever in Findochty and with an tbreak of scarlet fever in Banff. The matron's salary s been increased from £40 to £50 per annum. In nsequence of the large number of typhoid fever patients multaneously treated the board had in August last to tain additional beds, bedding, and furnishings. At the me time the ordinary staff of the hospital had to be sup- emented for some time by two extra nurses and a laundry- aid. The board is engaged in considering the necessity providing additional drying accommodation in connexion ith the hospital laundry and some other arrangements to hich the medical officer called its attention during the year.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Infectious Disease in Belfast.

THE question as to where patients suffering from infec- us disease are to be located in Belfast has for some ce been a controversial one between the Belfast board of ardians and the public health committee. Up to last year such cases were treated at the fever hospital in connexion th the union workhouse, with the exception of a few cases typhoid fever which were treated at the Royal Victoria spital. Since the new municipal fever hospital at Purdys- rn has been available the guardians have asked that all their er patients should go there in order to remove the risk of ection from the vicinity of the 4000 people in and about the ion workhouse, which is situated in the centre of Belfast. appears that in the North and South Dublin unions they ve no infectious diseases treated at the workhouse. It was ted at a meeting of the Belfast board of guardians on pt. 17th that there were 31 cases of typhoid, or typhus, er and other infectious diseases in the union fever hospital d 46 patients in the city fever hospital at Purdysburn. e guardians want to know why, after the ratepayers have gone to such great expense in building outside the city a municipal fever institution, so many infectious cases still remain in the union fever hospital in the heart of Belfast. They are determined to pursue the matter until all the patients suffering from infectious diseases are transferred to the city fever hospital. A lengthened discussion took place on the question at a meeting of the public health committee held on Sept. 19th, when it was decided to ask the guardians to supply returns of the maximum number of each class of infectious diseases under treatment in the union hospital at any one time during the past ten years and this would give an idea of the accommodation that should be provided if the union hospital authorities made an arrangement with the committee to take charge of patients suffering from any of the notifiable diseases. The truth of the matter is quite clear: when the municipal authorities erected an infectious diseases hospital they made it too small, under the impression that such cases up to a certain number could be treated in the union fever hospital, to which, naturally, the guardians object.

Belfast Union Consumption Sanatorium.

The formal opening of the Abbey Sanatorium in connexion with the Belfast workhouse took place on Sept. 19th, the chairman of the board of guardians performing the ceremony. The site cost £5000 and £30,000 have been spent in erecting and equipping the buildings. One section of the building is for the accommodation of early cases and the other is for advanced cases. In the former the average number of cases will be 120, and in the latter 150. There are an administrative central building and four separate pavilions and a hospital block. Around the buildings there are 33 acres of land. When fully equipped it is hoped to have all the workhouse consumptives located in this new sanatorium. This institution reflects the utmost credit on the Belfast guardians.

Queen's College, Belfast: Opening of New Laboratories.

Owing to the sudden illness of Lady Kelvin Lord Kelvin was unable to open, as had been arranged, the new laboratories at Queen's College, Belfast, on Sept. 20th, but his nephew, Mr James Thompson, M.A., read his address. The President of Queen's College presided, and having referred to the seven laboratories to be opened that day and to the disappointment felt at Lord Kelvin's enforced absence, called upon his nephew, Mr. James Thompson, to read Lord Kelvin's address, which he did. Sir Otto Jaffe then formally declared the laboratories (chemical, physical, engineering, physiological, pathological, biological, and pharmacological) open. Sir Christopher J. Nixon, Vice-Chancellor of the Royal University, moved a vote of thanks to Lord Kelvin, Mr. Thompson, and Sir Otto Jaffe, which was seconded by Professor E A. Letts, Ph.D. A gold key intended for Lord Kelvin was presented to him through Mr. Thompson. The National Anthem having been sung, a very large company was entertained at a garden party within the college grounds by the president and professors, when the new buildings, which were thrown open for inspection, were visited and greatly admired by the guests. In his address Lord Kelvin referred to the fact that never on one day and in one university were seven laboratories opened for scientific instruction and research; consequently it was, in his opinion, a unique day in university history.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis Problems.

TWO interesting questions relating to tuberculosis but differing considerably in their essential aspects have recently claimed attention The first one had reference to a man who, after being in the service of a railway company for 17 years, had been dismissed as tuberculous and therefore unfit for the work. He thereupon brought an action for damages against the company. An expert was appointed to inquire into the facts and the court awarded the plaintiff 5000 francs on the ground that his unfitness for active and regular work had not been in any way proved because the progress of the disease from which he suffered was slow and he was strong enough to follow his employment. The other question had reference to an antituberculous dispensary. I have already mentioned in THE LANCET that the authorities had resolved

to establish at the Hôpital Laennec a sanatorium for the treatment of pulmonary tuberculosis and to combine with it a dispensary for the benefit of patients suffering from tuberculosis but not able to be admitted to hospitals. In consequence of this decision petitions were sent to the Minister of Public Instruction by the local residents who feared that the children attending a school in the same street, but at a distance of 150 metres, would be in danger of infection. The Conseil d'Hygiène et de Salubrité of the department of the Seine on hearing of this complaint requested M. Letulle to make a report. In this report, which was unfavourable to the prayer of the petitioners, M. Letulle said that in the practical working of methods for the prevention of tuberculosis it was universally found in all countries beyond the possibility of doubt that antituberculous dispensaries were not a danger to the neighbourhood. On the contrary, their effect is to reduce the number of cases of pulmonary tuberculosis and thereby to render the neighbourhood of the dispensaries more healthy.

Transmissible Diseases in Communal Schools.

The Minister of Public Instruction has recently addressed to the prefects a circular in connexion with the precautions to be taken against certain infectious and contagious diseases in the primary public schools. The Minister states that for the purpose of putting an end to a state of uncertainty which might cause uneasiness to families he has resolved to remove *pelade* (alopecia areata) from the official list of contagious diseases; this arrangement has also the approval of the Conseil d'Hygiène et de Salubrité of the department of the Seine. Specific directions are given as to the course to be taken when the following diseases make their appearance in the schools. Children attacked with small-pox or scarlet fever or diphtheria must not return within 40 days; their books and copy-books must be destroyed; and general disinfection must be carried out. In the case of small-pox all the teachers and pupils must be revaccinated and in the case of scarlet fever the school must be temporarily closed if several children fall ill within a few days notwithstanding all precautions. Children attacked with measles must not return within 16 days, their books and copy-books must be destroyed, and if necessary the school may be closed to children under six years of age. Children attacked with epidemic parotitis or whooping-cough must not return within ten days and three weeks respectively. Children affected with tinea must not return until they have received appropriate treatment and have had dressings applied.

The Treatment of Deformities Caused by Tuberculous Disease.

A large orthopædic institute has been established at Berck by Dr. Calot for the treatment of tuberculous diseases of the bones and superficial structures, deformities, dislocations, and coxalgia. Berck is a seaside place in the department of the Pas de Calais; its climate is naturally suitable for this class of patients and Dr. Calot's method of treatment has had a gratifying amount of success. This year he has arranged a series of clinical demonstrations (*conférences*) at which all the details of treatment and all the difficulties likely to be encountered are explained; the process of making and applying various forms of apparatus is also shown upon patients. The daily course of instruction consists of a preliminary discourse lasting for a quarter of an hour and practical instruction for two hours. These courses are well attended by medical men. Dr. Calot attaches much importance to early diagnosis of the diseased condition and steady perseverance in the treatment selected.

The Medical Examination of Military Recruits and the Workmen's Insurance Law.

IN Germany every young man in his twentieth year has to present himself before a commission consisting of military men and civilians in order to be examined by an army medical officer as to his fitness for military service. This is for a great many young men the first medical examination which they have undergone, and sometimes morbid conditions are discovered of which the man himself was not aware but which, of course, prevent him from entering the army. In order to make these examinations as far as possible useful for the young men thus rejected the Government has decided that in cases where the army medical officer has found some morbid condition which might by appropriate treatment be prevented from becoming worse he shall be authorised to give notice to the authorities of the workmen's sickness insurance organisations in order that they may, if necessary, give attention to the case. This coöperation of the military medical officers with the civilian health authorities will be advantageous to young men in the early stage of pulmonary tuberculosis, as well as to those suffering from other disorders or abnormalities of the lungs, the circulation, the eyes, and so on. The army medical officers are not required either to undertake the correspondence with the insurance offices or to make any suggestions as to the precautions which ought to be taken, since either of these duties would add considerably to their work. They have only during or after the meeting of the recruiting commission to give its civil president the names of the men who seem to require medical attention. The president of the commission will then send a list of these men to the district insurance office (Landes-Versicherungs-Anstalt) which has to decide on the case. Furthermore, when a soldier has been dismissed from the army for some chronic disease during his period of service the military authorities have to notify the case to the district insurance office. These regulations, of course, concern only men earning less than 2000 marks per annum, as they are the only men coming under the provisions of the law relating to insurance against sickness.

Disinfection of the Hands.

Professor Klapp and Dr. Dönitz of the Berlin Surgical Clinic, writing to the *Deutsche Medizinische Wochenschrift*, recommend a new proceeding for the disinfection of the hands of the surgeon and the field of the operation respectively. They point out that the various endeavours that have hitherto been made to produce absolute sterility of the skin by means of chemical agents have failed because germs are left in the folds of the skin. Some surgeons therefore wear gloves during an operation and it has also been proposed to protect the skin with an impermeable covering through which germs could not penetrate. This principle is a very reasonable one, although the practical execution of it is difficult, especially for the skin of the surgeon's hands. Professor Klapp and Dr. Dönitz have now devised a method by which the bacteria are, as it were, imbedded in an impermeable substance. For this purpose they use a solution of wax which in their earlier experiments was dissolved in ether, but they afterwards preferred tetrachloride of carbon as the solvent, being cheaper and less inflammable than ether; this solution, which is termed "chirosoter," is sprayed over the hands by a spray-producer, and when the solvent has evaporated a thin coating of wax is left on the skin. Water, pus, blood, and other fluids now run off the skin just as from oil-paper. It is essential that the skin should be as dry as possible previously to the application of the chirosoter, and therefore a previous disinfection by alcohol, spirit of soap, and similar dehydrating agents is recommended. The coating of wax remains in good condition for a considerable time and is not affected by washing with soap and water. After the operation the wax should not be removed from the hands as it is an excellent cosmetic agent, making the skin soft and smooth. The practical results obtained by this method in a large number of operations are said to have been very good. It has also been found useful in fresh wounds, such as division of tendons, where the surroundings were covered by chirosoter without any other disinfection. Bacteriological examination of the skin showed that the germs present in it were greatly reduced in number.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Tuberculosis.

ON July 21st the Swiss Central Committee for Combating Tuberculosis held its fifth annual meeting at Olten. The committee is doing energetic work by forming active sub-committees in the cantons of Bern, Nidwalden, Glarus, Freiberg, Solothurn, Appenzell, Waadt, and Neuchâtel. In eight other cantons the sanatorium committees have undertaken the work and in three other cantons the local sanitary authorities have done so. A women's gentleman, who was under examination for a long time, had two points closely connected with one another to deal with: the question whether there had been life in the sense required by the law, and that of how such life had been terminated. With regard to the former the flotation of the lungs was mainly relied upon, the test having been carried out by the removal of the whole of the contents of the thorax, including a large thymus, and the placing of them in water after ligaturing the vessels, when it was found that the lungs contained sufficient air to prevent the mass from sinking. On the second point the question at issue resolved itself into whether the grandmother had strangled a live child with a cord procured by her for the purpose, or whether, as she had alleged, she had found her granddaughter delivering herself of a child already dead, or almost dead, through the winding of the umbilical cord twice round its neck, and had only then assisted in completing the delivery, by which time the child was found to have been stillborn. The grandmother had practised as a midwife until the passing of the Midwives Act, when apparently she had not sought registration. The evidence as to the intentional strangulation with a foreign substance rested on the features presented by a grooved line running round the neck of the exhumed body. This was described by Mr. Price as a well-marked groove about a quarter of an inch in width, with raised hardened edges, and higher at the back of the neck than in front, the examination of it having led him and Mr. Lyster to the conclusion that a foreign substance and not the umbilical cord must have caused it. Death they assigned to strangulation in the manner indicated, combined with hæmorrhage from the umbilical cord, the evidence of which was duly described. The evidence of the two witnesses named was corroborated by that of Mr. A. J. Pepper, called as an expert. For the defence, the statements of the prisoner, Mrs. Webb, were given weight to by Dr. F. J. Smith who gave evidence to the effect that the physical phenomena observed and described by the medical witnesses for the Crown were not conclusive as to her guilt but were at least consistent with her story being true, and he himself expressed the opinion from the facts described that the child was stillborn owing to strangulation or suffocation during protracted delivery. He did not regard the evidence of separate existence derived from the flotation of the lungs deposed to as conclusive. His views were supported by Dr. H. Russell Andrews who agreed with him in thinking that the mark described upon the neck might or might not have been caused by the umbilical cord. In these circumstances the jury, after retiring to consider the evidence, acquitted the prisoner Webb of the charge of murder but convicted her and her granddaughter of concealment of birth, for which offence they were each sentenced to six months' imprisonment with hard labour.

An Action to Recover Fees.

The executors of the late Mr. O. J. Oldham, F.R.C.S., recently sued an elderly lady, Mrs. Fraser, residing at Byron Hall, Worthing, for the balance of an account for £168 for attendance and for performing an operation. Mr. Oldham at the time when the debt was incurred lived at Hove, Brighton, and the amount was made up of charges of 3 guineas each for 19 visits to his patient at Worthing, a distance of about ten miles, a hundred guineas for the operation, and 3 guineas for the anæsthetist's fee. The operation was performed in January, 1901, and the account was sent in frequently after Mr. Oldham's attendance upon his patient ceased towards the end of that year. One of her sons, Captain Fraser, appe to have thanked Mr. Oldham for his kindness and to have mentioned family difficulties as a reason for not paying the account. It remained unsettled for some time, but finally, after a solicitor had intervened, bills for £40 payable at intervals of three months were given and two of these were met. Mr. Oldham died in January, 1907, and his executors brought the action to recover the balance due and the defendants not only resisted this but set up a counter claim for part of the money which they had paid on the ground that they had not known that the sum of £100 represented the operation and that it was excessive. Another son, Major Fraser, in addition to the one already mentioned, went into the witness-box and gave evidence as to this, informing the court that their mother was the widow of an officer in the army enjoying two pensions as such, amounting to £460 a year. One of these gentlemen characterised Mr. Oldham as a "local practitioner" who should not have charged a widow lady £100 for a single operation. His Honour Judge Woodfall, in summing up, pointed out that there was nothing in the evidence given to show that the charges were excessive and paid a tribute to the medical profession, dwelling upon their readiness to reduce their charges or to make none in cases of real necessity. A verdict was found for the full amount claimed by the executors, for which judgment was given with costs.

IMPERIAL CANCER RESEARCH FUND.

THE annual meeting of the general committee of the Imperial Cancer Research Fund was held on July 1st at Marlborough House, the PRINCE of WALES presiding. Among those present were: Sir William S. Church, Sir Julius Wernher, Sir Charles Morrison Bell, Sir Richard Douglas Powell, Sir Henry R. Swanzy, Sir Henry G. Howse, Sir John McFadyean, Mr. H. L. Florence, Dr. John Tatham, Dr. J. Rose Bradford, Mr. H. T. Butlin, Mr. W. Watson Cheyne, Mr. J. A. Mullens, Mr. Henry Morris, Mr. Ludwig Neumann, Mr. S. Neumann, Mr. Edmund Owen, Mr. H. J. Stiles, Dr. E. F. Bashford (general superintendent of research), Dr. J. A. Murray, Dr. Haaland, Mr. W. H. Bowen, Mr. E. R. Frere, and Mr. F. G. Hallett (secretary).

Sir WILLIAM CHURCH, in moving the adoption of the report, said that the investigation into the cause, nature, and treatment of cancer had, during the past year, followed the same lines as in former years. Owing to the valuable assistance received from the Governments of India and other dependencies, as well as from the Foreign, Colonial, and India Offices, and from private sources, their knowledge of the existence and frequency of cancer in various races of men was steadily increasing; and its presence was found to be associated not infrequently with native customs or religious rites which acted as sources of chronic irritation of portions of the surface of the body. Statistical information continued to be collected from London and provincial hospitals. Reports of 1282 cases (rather more than a quarter of the total deaths from cancer in the metropolitan area) had been received from the London hospitals and 392 from provincial hospitals. The probabilities of cancer manifesting itself in individuals and in families in persons over 35 years of age had been made the subject of calculation. 20 years ago Dr. William Ogle, then statistician to the Registrar-General, stated that one out of 21 men reaching the age of 35 years and one out of every 12 women reaching the same age eventually died from cancer. From the Registrar-General's report for 1905 it had been calculated that at the present time, of men over 35 years of age one in 12 would eventually die from cancer and one woman in every eight who attained to the same age. These figures were higher than those given by Dr. Ogle, and the numbers of cases in the two sexes were approximating, which might be due to the fact that women suffered from forms of the disease more easily recognisable than was the case in men. It was impossible to say how far this apparent increase in the number of persons affected arose from a real increase in the frequency of the disease or from its more frequent recognition now as the cause of death. In man, owing to the length of life, the low rate of fecundity, and the varying value of the records, there were no means of obtaining from the records of preceding generations the facts with anything like scientific accuracy. Experiment was necessary in order to trace more accurately the circumstances associated with the spontaneous occurrence of cancer both in individuals and in families. It had now been found possible to establish strains of mice from cancerous parents. The removal by surgical means of cancerous tumours occurring spontaneously in mice prolonged their lives and had enabled young ones to be bred from them; they had, therefore, now the means of observing descendants of mice of known cancerous parentage, and by successively crossing other spontaneously affected animals with the offspring of cancerous parents, the hereditary tendency, if there was any, could be concentrated. This concentration in large numbers of animals of a known age should enable them, in the course of a few years, to determine whether there was a family tendency or only an individual tendency to the disease. At this part of his address Sir William Church summarised the experimental work accomplished in the laboratory during the past year. Our comments on these investigations will be league for combating tuberculosis has been founded and hygienic societies have offered their support. Thus there is progress on all sides. Another paragraph is to be added in the new Swiss Insurance Law for workmen, with special reference to increased support in cases of long standing illness. Dr. Sandoz, Dr. Kürsteiner, and Dr. Mallart spoke about the antituberculous dispensaries which have been organised in Neuchâtel, Bern, Lausanne, and Geneva. In Neuchâtel two medical men and a nurse are attached to the dispensary; medical treatment is not undertaken but advice is given regarding prophylactic steps to be adopted. The dispensary supplies spittoons and disinfectants; gives aid in the shape of food, fuel, bedding, &c.; disinfects apartments; and provides for patients in sanatoriums and country homes. In Lausanne and Geneva medical treatment is also provided through the out-patient departments of the University hospitals. Similar dispensaries are to be established in various other Swiss towns.

Medical Students at Swiss Universities.

The number of medical students at the five Swiss universities has again considerably increased. For the summer term 2075 students were on the lists as compared with 1884 in the previous summer. Only 567 were of Swiss nationality, 1508 being foreigners, principally Russians. Energetic steps are being taken by the various university authorities to reduce the number of foreign students. The fees have been increased and the entrance examinations have been made more difficult. The number of students at the universities in the several cities was as follows: Basle, 175 (two ladies); Bern, 533 (334 ladies); Geneva, 445 (241 ladies); Lausanne, 435 (301 ladies); and Zürich, 492 (210 ladies).

Zürich, Sept. 20th.

ITALY.

(From our own Correspondent.)

A Sanitary Reawakening.

On Sept. 20th, 1870, Rome became the capital of United Italy and yesterday's celebration of the event was conspicuous as compared with the 36 previous celebrations, for the tranquility of the proceedings and the high tone, intellectual and moral, that pervaded the oratory. Abuse of "priestcraft," "obscurantism," and "mediæval superstition"—the *loci communes* of former commemorations—was replaced by serious discussion of Italy's requirements, prominent among which are public instruction and public hygiene, beginning in both cases with the child. And, indeed, the discussion has begun not a day too soon. Education, particularly in its earliest stages, is still deplorably defective, and even if the teaching personnel and equipment were more efficient they are heavily handicapped by the sanitary conditions of the accommodation and, above all, by the state of health of the child. Go into any school, urban or rural, attended by the poorer classes and one of the first things that strike you is the number of "adenoids"—victims to naso-pharyngeal obstruction—among the scholars. The "facies adenoidea" (of recent Italian nomenclature) meets you at every turn—betrayed by the pallor, the low vitality, the hebetude alternating with a false vivacity, the "bocca semi aperta" (half-open mouth), and other symptoms to which the next remove is cretinism. Stand near one of these little pupils and, particularly if he is interested in his task, you can hear his buccal respiration—or "snoring awake," as it has been called. He seems suffering from a chronic cold in the head (*costipazione di testa* is the expressive Italian word for it) and on a nearer look at him you as often as not detect conjunctivitis, lacrymation, or redness of the *margines palpebrales*. In a word, the little man is a victim to those "vegetazioni adenoidei" the result of malnutrition operating on a physique often septic by transmission and reinforced by foul air in the dormitory or in the school itself. The air passages surcharged with this dense mucosity affect the pronunciation, particularly of the nasal vowels and the labial consonants, ending in stammering, stuttering, or positive non-articulation. "Sordità adenoidea" is another symptom due to the same cause and this "deafness" is often found in the proportion of from 20 to 30 per cent. of the attendances. Teacher and pupil alike are thus baffled in their work by causes purely physical and the wider interests of education are compromised by what might be avoided by previous medical surveillance and treatment. That Italy has awoke to increased solicitude in this direction on the part of parents particularly is manifest from the discussions of this very subject in the lay press and from the prominence which it occupies in the programme of the Physio-Therapeutic Congress to be held next month in Rome.

Vegetarianism.

Any movement that makes for intelligent alimentation in food or drink must be welcomed in Italy, where "use and wont" of the most uninquiring or credulous kind have long dictated the *cuisine*. Discussion as to the good or evil to be derived from a diet exclusively vegetarian draws Italy's attention to a field in which she has hitherto fallen much below her opportunities, and this is already one of the gratifying results to be deduced from the opening of "vegetarian restaurants" in the capital. One of these celebrated its "trial trip" on Sept. 19th and the presence of not a few general practitioners and consultants attested the interest taken, professionally as well as socially, in the new departure. The *menu* was compiled from purely vegetable sources, salt was taken very sparingly, and wine was officially excluded. It is true that under these two heads—salt and wine—there was a little mutiny on the part of the guests, some of whom were allowed to gratify their tastes, though in the strictest moderation; but, on the whole, the symposium was a success and, though far from conclusive as solving the question whether, or to what extent, vegetarianism is sound dietetics, it had the collateral recommendation of proving how palatable and even sustaining the "kindly fruits of the earth" may be made by skilled cookery and how an increased demand for the said "fruits" may be instrumental in raising Italy to the position which nature intended her to occupy—that of the "market garden" of Southern Europe.

Sept. 21st.

BUDAPEST.

(From our own Correspondent.)

A Sanatorium conducted by a Limited Liability Company.

A prominent member of the medical profession has hit on the idea of forming a limited liability company for founding a sanatorium. In Budapest the want of a modern sanatorium where patients of the better class could be accommodated has been felt for a long time and for this reason the idea of carrying on a sanatorium under the management of a company has met with the general approval of the medical profession. The share capital will be a little more than £20,000, divided into 2000 shares. For the first two weeks shares can only be subscribed for by medical men, but they may afterwards be taken up by the general public. Every shareholder has the right to use the sanatorium for one week in a year at half the usual charges. Patients under the care of shareholders will be considered in the first place, and other patients will be accommodated after those under the care of shareholders have been provided for. The sanatorium will be furnished with every modern convenience and a variety of baths, including pine, carbonic acid, Nauheim and Turkish baths. There will also be lying-in wards and two operating theatres. The directorate consists of a surgeon, a gynæcologist, a clinician, and a dermatologist. The charges made for rooms, including nursing and full board, will be most moderate, something about 5s., 6s., and 10s. per day, but the directors nevertheless promise 17 per cent. net dividend, even if all the rooms are occupied only on 300 days per annum.

Lumbar Anæsthesia in Gynæcology.

Dr. Avarffy has published the results of some trials of lumbar anæsthesia which were made in the clinic of Dr. Bársony, professor of gynæcology. He says that the results were very satisfactory. Lumbar anæsthesia, like general anæsthesia by inhalation, has its risks, and there is also a possibility of doing some harm if great care is not taken, especially in observing the special conditions of individual patients. Statistics which exhibit a greater mortality under lumbar anæsthesia than under anæsthesia by inhalation are erroneous, because it is a generally accepted fact that cases of asphyxia, difficult breathing, and collapse are much more frequent during the latter than during the former. The result that the income and expenditure account showed a surplus of £836 4*s.* after a further sum of £771 7*s.* 9*d.* in connexion with the drainage and sanitary operations had been deducted. The amount expended on these extensive but necessary works had reached the large total of £8000, and in order to provide this the council had had to part with all stocks belonging to the General Purposes Fund, the only remaining asset being sundry mortgages amounting to £2550. The council regretted to announce that they had lost by death five members of their body—namely, Dr. M. Baines, Sir Joseph Fayrer, Bart., M.D. Edin., K.C.S.I., F.R.S., Mr. D. H. Goodsall, Sir A. W. L. Hemming, G.C.M.G., and Sir Arthur T. Watson, Bart., K.C.; and that Dr. P. W. Latham of Cambridge had felt himself compelled to resign his seat on the council owing to the difficulty of finding the time necessary for the work. Reference was also made to the loss which the College had sustained by the death of Mr. Thomas H. Wakley, F.R.C.S., a vice-president. Since the last annual general meeting the "Robert Armstrong Scholarship" of £60 a year for classics, tenable for three years at the University of Oxford or Cambridge, had been founded, and a legacy of £1000 had been received recently to found the "R. R. Cheyne" annuity for daughters of medical men who are Protestants. The report on the discipline, work, and health of the school was a very satisfactory one. Mr. H. F. Lee, one of the masters, had most kindly presented to the school a sub-target rifle, which would no doubt prove of great value as a means of instruction in rifle shooting. Since the last report S. H. Fazan had obtained a classical exhibition at Wadham College, Oxford, and had since been elected to an open scholarship of £80 at Christ Church; Ff. Roberts had gained a science exhibition of £30 at Clare College, Cambridge. 14 boys had passed the whole or a part of the preliminary scientific examination for the degrees of M.B., B.S. of the University of London; 16 boys had passed the matriculation examination of the same University; 13 boys had gained the higher certificate of the Oxford and Cambridge schools examination board and 37 had gained the lower certificate.

In proposing the adoption of the report for the past year the chairman drew attention to the salient points contained therein and specially referred to the great loss which the council had sustained by the deaths of two members of their body—namely, Sir Joseph Fayrer, who had been interested in the College since the year 1858 and had acted as chairman of the council for 14 years; and Sir Arthur Watson, who had been for 20 years a member of that body, during which period his professional advice was placed unreservedly at their service. He also made special reference to the loss experienced by the College by the death of Mr. Wakley, who had taken a very great interest in the institution since its foundation, and who had rendered material support when the desirable and beneficial change was made by which annuitants were entitled to receive an augmented pension in lieu of rooms in the College at Epsom. He reported the recent receipt of a legacy of £5000, from which the duty had to be deducted, under the will of the late Mr. Charles James Oldham, F.R.C.S., of Hove and observed that absolute requirements at the College in the way of accommodation for science teaching and necessary alterations and additions to the buildings would exhaust that sum, as well as any other gift of a substantial amount that might be received. In conclusion, he stated that the number of boys at present in the College—namely, 263—was the highest on record, and he drew attention to the fact that the greater facilities for the admission of day boys which were provided by the council last year had resulted in an increase in their number, there being at present 20, whilst the lowest point touched in 1906 was 12.

The motion having being adopted, formal business was transacted, including the re-election of members of the council, election of auditors, and alterations and additions to the by-laws.

A vote of thanks to the chairman, moved by Sir WILLIAM CHURCH, and seconded by Sir DOUGLAS POWELL, brought the proceedings to a close.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LEICESTER-SQUARE, LONDON, W.C.—The silver medal (instituted in 1895 by the Earl of Chesterfield, President of the hospital) has been awarded to Mr. E. J. D. Mitchell, M.A., M.B., B.C. Cantab., for proficiency in dermatology.

ASYLUM REPORTS.

Derby Borough Asylum (*Annual Report for 1906*).—On Jan. 1st, 1906, there were 331 patients in the asylum; of these 149 males and 157 females belonged to the Derby union, and three males and 22 females were scheduled as private patients. During the year 98 persons (46 males and 52 females) were admitted; of these 84 (44 males and 40 females) were chargeable to the Derby union. The average annual admission of rate-supported patients has been 83 for the last five years and 76 since the opening of the asylum, 18 years ago. 47 patients were discharged: as "recovered," 35 (12 males and 23 females); as "relieved," six (two males and four females); and as "not improved," six (two males and four females). The recoveries are at the rate of 41·17 per cent. of the admissions (excluding transfers from other asylums), 30·0 for men and 51·11 for women. There were 37 deaths recorded during the year, 19 males and 18 females, being 11·1 per cent. on the daily average number of patients resident; of these 10 were cases of general paralysis. Dr. S. Rutherford Macphail draws attention to the fact that as the rate-supported patients are increasing at the rate of 10 annually, and as there are now only five vacancies on the male side and six on the female side, the extension of the asylum cannot be delayed much longer. The weekly rate of charge to the Derby board of guardians was reduced on Jan. 1st from 11*s.* 1*d.* to 10*s.* 6*d.* per patient. Private patients are charged 17*s.* 6*d.* and 21*s.* weekly. The farm and garden account shows a credit balance of £273.

Barming Health Asylum, Kent (*Annual Report for 1906*).—The number of patients on the books of the asylum on Jan. 1st, 1906, was 1489 (682 males and 807 females). During the year 1906 there were 407 admissions (180 males and 227 females), the rate of increase being below the average. Mr. H. Wolseley-Lewis has drawn up a table showing the number of patients for whom accommodation has had to be provided during the last 20 years. He states that during the last 16 years, since Lewisham, Greenwich, and Woolwich ceased to belong to Kent, the population of the insane has increased by 874, or on an average of 54·6 patients per annum, and as during recent years the increase has been higher he considers that it is safe to assume that an increase of over 50 beds a year will be necessary in future. Owing to the outcry about the increase of insanity during recent years Mr. Worsley-Lewis has made an analysis to see whether there has been any real increase in West Kent. Taking the figures for the last 15 years of fresh cases of insanity admitted to Barming Heath Asylum he finds that a slightly diminished rate is to be observed, and adds that "when it is borne in mind that many cases are now sent to asylums who previously were kept at home or in the workhouses, and that the population has increased by some hundreds of thousands, this lessened frequency of the incidence of insanity becomes well worth attention." On the other hand, he finds that there is an increase in the number of relapsed cases which are re-admitted. Referring to the causation of the insanity in those admitted during the year 1906, 112 are known to have had an insane inheritance and 42 were senile dements. 199 persons were discharged during the year (89 males and 110 females); of these, 156 (66 males and 90 females) left the asylum recovered, thus giving a recovery rate of 41·3, which is the highest with one exception for 14 years. 11 persons (four males and seven females) were discharged "relieved" and 32 patients (19 males and 13 females) "not improved." There were 186 deaths recorded (92 males and 94 females), giving a death-rate of 12·4. There has been no outbreak of infectious disease during the year. Owing to the satisfactory financial state the maintenance-rate has been reduced 10½*d.* per head per week.

Chartham Asylum (*Annual Report for 1906*).—The number of patients on the books of the asylum on Jan. 1st, 1906, was 1061 (487 males and 574 females). There were 226 persons admitted during the year (114 males and 112 females), making the admission rate about an average one. The discharges numbered 117 (54 males and 63 females). Of these, 85 (36 males and 49 females) left the asylum as "recovered," giving a recovery rate of 48 per cent. for females and 32 per cent. for the males. 12 patients were discharged as "relieved," six of each sex; 18 left "not improved" (ten males and eight females); and two males were returned as "not insane." The number of deaths recorded were 131 (68 males and 63 females), the death-rate being 13·8 per cent. on the male after-effects of lumbar anæsthesia are also much less serious than the vomiting and pneumonia which so often follow chloroform anæsthesia.

Medical Congress in Pozsony.

A medical congress has just been held in Pozsony, a large city on the Danube wrongly known abroad by its German name of Pressburg. The proceedings commenced on August 27th, with Count Apponyi, Minister of Public Instruction, in the presidential chair. The first address was delivered by Dr. Fisher who spoke on Moral Insanity. He said that this was a mental disease and therefore those suffering from it could not be made accountable for their actions before a court of law. They must be regarded not as criminals but as patients. Dr. Konrad said that there were persons who might be truly described as born criminals. They were, however, not a distinct species of the genus homo but were degenerates. Persons suffering from the so-called moral form of weak-mindedness formed a permanent element in the prison population. They ought not to be admitted into asylums for the insane because they would exert a disturbing influence on the work of such asylums and to keep them in prison would be unjust. The first duty of the law was to protect the community and "anti-social" persons who were at war with society should be banished to distant self-maintaining colonies. Dr. Detre, lecturer at the university of Budapest, showed a new method, devised by him, with the help of which it was possible to decide within 24 hours whether the bacilli with which a tuberculous patient was infected were of human origin or were derived from the lower animals or whether there was a double infection. Dr. Bilasko, assistant-surgeon of the dental clinic, read a paper on anæsthetics in dental surgery. In an address on "The Cosmetic Aspect of Tattooing" Dr. Emil Weyner said that tattooing was extensively applied in dermatological practice for concealing facial scars, and that it was very much in fashion in the army. In the Austro-Hungarian Army almost every soldier was tattooed. Dr. Weyner claims to be the first medical man in the world who tattooed the eyelids.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Cholera.

ALL the interested authorities in the Turkish metropolis, such as the Conseil Supérieur de Santé, the Conseil Supérieur d'Hygiène, and the municipalities of different districts, are taking very energetic and extensive measures to prevent the epidemic of cholera which is still raging in several provinces in Russia from invading Ottoman territory. Strict quarantine is imposed upon every steamer and sailing-boat coming from the Black Sea. Ships from Odessa are subjected to three days' quarantine. A special commission has been sent to Sinope on the Black Sea in order to enforce all the quarantine measures of prevention which have been decided upon in Constantinople. Ships bringing Russian pilgrims for the Hedjaz railway will not be allowed to touch at any port on the Bosphorus or the Dardanelles and will have to go directly to Abu-Saad, where they will be subjected to 48 hours' observation and the requisite forms of disinfection. Should, however, a case of cholera manifest itself on board ship during the voyage from Russia to Cavak on the northern entrance to the Bosphorus the ship will be sent back and will have to visit the lazaret at Sinope in order to undergo all the necessary measures provided for the exigency. Should a case of cholera occur beyond the strait of the Bosphorus the steamer will be directed towards the lazaret of Glazomene. Not only pilgrims but also ordinary passengers will have to submit to the same measures. After the quarantine at Sinope passengers will also have to undergo a medical inspection at Cavak. The same will be the case with steamers and passengers coming from Batoum and Sebastopol. In Russia the cholera seems to spread. Eight fatal cases occurred this week at Saratow, 13 at Tsarizin, and 10 at Nijni-Novgorod.

The Hamidié Hospital.

This hospital has issued its *Annales Médicales*. It is a big volume full of interesting information and of beautiful illustrations. It contains original articles by eminent European medical men and an able monograph on "Un Cas de Hernie Diaphragmatique" by the well-known Constantinople surgeon Dr. Cambouroglou Pasha. From these reports it appears that the Sultan has spared neither money nor energy to make his hospital a perfect and in every way an up-to-date establishment. New buildings have been recently erected at great cost. The pavilion for women has received special attention. Mention is made in the volume of the new sanatorium to be erected at Kutahia in Asia Minor. This sanatorium is intended primarily for tuberculous patients. It will be built in the centre of an extensive pine forest on a high elevation upon the plateau of Kutahia which is reputed to possess an abundance of excellent springs. The air of the place is pure and the scenery is magnificent. It will be under the control of the medical authorities of the Hamidié Hospital, thus forming, as it were, a branch of this establishment. A new large edifice with a chemical and analytical laboratory has been added, as the old one proved to be insufficient. The hospital, with all its branches, is under the direction and management of Dr. Ibrahim Pasha, physician to the Sultan.

The Water-supply of Damascus.

It is reported from this city that the work of canalisation for the purpose of supplying it with good drinkable water was begun last month. Up to now Damascus has been provided with water from the Chrysorhoas or the so-called "gold river" of the ancient Greeks, named at present Barada. This river, the Abana of the Bible, intersects the city with its several branches. In olden days there existed an admirable system of channels and pipes, by which water was conveyed through every quarter and almost into every house. There are also numerous wells. The distribution used to take place in a very ingenious manner. It is said that Abana is the life of Damascus and that it has made it perennial. It is also used very extensively for irrigation of the innumerable orchards, gardens, and vineyards and fields that are found in a circuit of at least 60 miles. Damascus and its surroundings owe their almost unrivalled beauty and luxuriance to the Abana. Yet its supply of water, though abundant, was not perfect from a sanitary and hygienic point of view. It has many a time proved to be the source of different epidemics. To remedy matters the former vali, Nazim Pasha, decided to construct canalisation works which would conduct to the city water from the famed source Ain Fijé, 20 kilometres from Damascus. These works, as already mentioned, have been commenced. A large reservoir will be constructed on the heights of Salhyé and the water which will be gathered up there will then be distributed to the different quarters by solid, extensive, and elaborate piping. Every municipal district will be provided with 26 public fountains.

Miscellaneous Notes.

The Sultan has conferred the gold and silver medals of the Imtiaz upon Dr. Zambaco Pasha who distinguished himself especially with his investigations and works on leprosy.—The *Ikdam* reports that a Mahomedan from Bitlis produced a birth certificate according to which he was born in the Turkish financial year 1190, being consequently 133 years old The man came to Constantinople in search of work. He does not look more than 60.—Last week's mortality returns show that 222 deaths took place in Constantinople, of which one was from scarlet fever, three were from diphtheria, three from small-pox, 12 from typhoid fever, 30 from tuberculosis, and one was due to cerebro-spinal meningitis.—Among the garrison of Tirnovo an epidemic of typhoid fever has broken out The number of deaths amounts to 60. It is feared that the town will be attacked by the epidemic.

Sept. 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Federal Text-book on Pure Milk Questions.

THE Agricultural Department at Washington has issued a volume of reports containing the results of the conference of experts called together by the department to consider the various questions now agitating the country in regard to the purity of the milk-supply. The conference consisted of 35 recognised experts in the study of the questions involved. This volume will be the recognised text-book of the health authorities of this country for the present, as it carries the respective numbers in the preceding week. Five inquest cases and five deaths from violence were registered; and 59, or more than 40 per cent., of the deaths occurred in public institutions. The causes of five, or 3·4 *per cent.*, of the deaths in Dublin last week were not certified; in London only *one* death was uncertified, while in Edinburgh the percentage of uncertified deaths was 11·6. The 135 deaths registered in Belfast during the week under notice included six which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: F. A. Brice to the *Good Hope* and E. A. Penfold to the *Terrible* on recommissioning. Staff Surgeon: G. Taylor to the *Terrible*. Surgeons: H. C. Woodyatt to the *Good Hope* on recommissioning; C. E. C. Stanford to R.M. Barracks Dispensary, Plymouth; and C. J. Boucher to the *Argonaut*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Arthur L. Jones to be Surgeon-Major (dated June 19th, 1907).

IMPERIAL YEOMANRY.

Royal North Devon (Hussars): Supernumerary Surgeon-Lieutenant W. F. L. A. Holcroft resigns his commission (dated May 31st, 1907). Edward Canny Ryall to be Surgeon-Lieutenant (dated May 28th, 1907).

VOLUNTEERS CORPS.

Royal Engineers (Volunteers): East London (Tower Hamlets): Surgeon-Lieutenant J. P. Stewart resigns his commission (dated May 28th, 1907). Edward Canny Ryall to be Surgeon-Lieutenant (dated May 28th, 1907).

Rifle: 19th Middlesex (St. Giles's and St. George's, Bloomsbury) Volunteer Rifle Corps: Supernumerary Surgeon-Lieutenant W. G. Macfee to be Surgeon-Captain, remaining supernumerary (dated June 4th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Woolwich Companies: Robert Corfe to be Lieutenant (dated June 1st, 1907). Black Watch Bearer Company: Lieutenant A. E. Kidd to be Captain (dated June 12th, 1907). Liverpool Bearer Company: Lieutenant S. H. House to be Captain (dated June 3rd, 1907).

THE BIRTHDAY HONOURS.

The following members of the Naval and Military Services have been the recipients of Birthday Honours—viz.: Inspector-General Herbert Mackay Ellis, K.H.P., director-general of the medical department of the Royal Navy, who receives a Knight Commandership of the Order of the Bath, and Colonel Charles Henry Beatson, I.M.S., Colonel George Deane Bourke, R.A.M.C., Deputy Inspector-General Thomas Desmond Gimlette, R.N., and Surgeon-General Francis Wollaston Trevor, A.M.S., each of whom has been made a Companion of the Order. Companionships of the Bath have also been conferred upon Surgeon-General Thomas Tarrant, K.H.P., A.M.S., retired; Deputy Surgeon-General Edward Malcolm Sinclair, late A.M.S., retired; and Deputy Surgeon-General Alfred Eteson, I.M.S., retired, in connexion with the fiftieth anniversary of the Indian Mutiny. Surgeon-Lieutenant-Colonel Warren Roland Crooke-Lawless of the Coldstream Guards, surgeon to His Excellency the Viceroy of India, has been made a Companion of the Indian Empire, and Dr. Jean Etienne Justin Schneider, principal medical officer of the first class in the French army and late chief medical officer to the Shah of Persia and president of the Sanitary Council of Persia, has been made an Honorary Companion of the same Order.

MR. GEORGE R. SMITHER, acting Consul-General at Barcelona, reports to the British Foreign Office that the Protestant Cottage Hospital, which has done excellent work in that city during many years, receiving as patients both Spaniards and foreigners, has made a new departure in the opening of an isolation ward for infectious cases; this will be a great boon as no such thing exists in the Barcelona General Hospital. The cottage hospital has proved often of great service to British sailors (especially in the convalescent stage) who are received for a small payment.

Correspondence.

"Audi alteram partem."

THE SURGICAL TREATMENT OF CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—*Having* heard that in some quarters there is feeling that my criticisms of Mr. Arbuthnot Lane's writing on the surgical treatment of constipation are too severe, should like to say that I have a *most friendly regard* for hi as a most amiable man and admiration for him as a practica surgeon. *It should* be remembered that the literature of th surgical treatment of constipation is almost wholly constituted by the writings of Mr. Lane. Nevertheless, it is no very small in quantity. *Therefore, when I had to deal wit* it and found that in my judgment (which, of course, may b worthless) its value was lessened everywhere by what seeme to me a tendency of Mr. Lane's to state his ingenious, an sometimes brilliantly clever, hypotheses just as if they wer proved theories and his views as if they were facts, it woul have required an intolerably lengthy and dull disquisition t argue about each in detail.

I feel sure no *complaint* will *come from* Mr. Arbuthno Lane, who himself is not unaccomplished in satire, as th following quotation shows: "*There* is a remarkable tendenc to ascribe to the appendix any tenderness present in or abou a line which extends from the anterior superior spine of th *ilium to the umbilicus and which has* been *dignified* with th name of a distinguished surgeon. Those making this mistake have, however, the satisfaction of knowing that if th appendix is not the cause of the trouble it is freely mobil and its excision involves practically no risk. It can b removed *through* a very small *hole*, the comparative minuteness of which gratifies them and the patient, suggesting grea operative skill."[1]

Now "those making this mistake" of "a remarkabl tendency to ascribe to the appendix any tenderness presen in or about" McBurney's point, are the majority of surgeon of talent and experience in the profession throughout th world, many of whom could be named. And they survey th scars of their "interval" appendicectomies in the manne suggested! However, I should feel obliged if you wil permit me to say that if any raillery of mine has cause the slightest pain or given offence to anyone of your reader I am sincerely sorry.

I am, *Sirs, yours faithfully,*

July 1st, 1907. C. B. KEETLEY.

To the Editors of THE LANCET.

SIRS,—I have read Mr. Keetley's lecture on "Conservativ Surgery of the Abdomen" with considerable interest and mixed feelings. I regard that lecture as an outburst o rectitude. I suppress Mr. Keetley's adjective because I giv him credit *for honesty*. But the *rectitude possesses* a angularity that may lead the budding surgeon who take Mr. Keetley as an apostle into devious devices and damaging disappointments. Mr. Keetley deals with three subject which he deems suitable for the application of surgical conservatism—*the fibroid uterus, the morbid appendix*, and the constipated colon. I may be bold, imprudent, or ignorant, but with 25 years' surgical experience behind me I venture to demur to some of the doctrines preached by Mr. Keetley to the West London Medico-Chirurgical Society. I will pass over the *first two subjects as not being germane* to the object of this communication.

In regard to the surgical treatment of chronic constipation I regret that Mr. Keetley did not confine his remarks to the *subject* of the treatment rather than to the *advocate* of the same. Mr. Keetley has placed "a brilliant teacher," a great surgeon, on a pillory, to be stared at or stoned by the casual passer-by, and while doing *so he has shown* that he has utterly misconceived or misrepresented the abnormal conditions that Mr. Lane's operation is designed to relieve.

Let me quote Mr. Keetley: "Now, if these were cases of genuine mechanical obstruction there is not much to say against the treatment and there need be no surprise at the results. But in the vast majority of *the cases of chronic* of authority of these experts and the endorsement of Department of Agriculture. In brief, these experts agreed upon a definite milk-programme and have recommended that public safety should be assured by legislation blishing three classes, or grades, of milk—namely, certified, pected, and pasteurised. They would not tolerate any ling with the public in the sale of so called certified lk. They would require that such milk should come dairies subject to periodic inspection and that the k should be frequently analysed; that the cows should be oved to be free from tuberculosis by the tuberculin test and m all other communicable diseases; that the milk should be dled by persons free from infection; that the milk should tain not more than 10,000 bacteria to the cubic centimetre; and that it should be not more than 12 hours old when livered to the consumer. The conference would permit e sale of such milk raw under the label "certified" and uld allow the sale raw, under the label "inspected," of lk that had been similarly produced but did not quite me up to the requirements for certification, provided that ch milk came in all cases from tuberculin-tested cows and l not contain more than 100,000 bacteria to the cubic timetre. Such milk, and only such, do these experts ieve should be sold raw; all other milk should be teurised. The declaration of the conference is as lows: "Milk from dairies not able to comply with the uirements specified for the production of milk of asses 1 (certified) and 2 (inspected) is to be pasteurised fore being sold and then sold under the designation asteurised milk.'" All milk of unknown origin shall be ced in Class 3 and shall be subjected to clarification and steurisation at central pasteurisation plants which shall be der the personal supervision of officers of the health partment. The term "pasteurisation" is explained to an the heating of milk to a temperature of 150° F. for minutes, or 160° for ten minutes, and immediate cooling 55°.

---

[1] THE LANCET, Dec. 17th, 1904, p. 1692.

Third International Sanitary Convention of the American Republics.

It is announced that the Third International Sanitary nvention of the American Republics will be held in the ty of Mexico from Dec. 2nd to 7th next. The first convention, held in Washington in 1902, was called in compliance ith resolutions relative to sanitary police adopted by the cond International Conference of American States, held Mexico in 1892. These resolutions were accepted as the sis for the work of the first Convention and resulted in he adoption of certain sanitary and hygienic principles nd the establishment of an International Sanitary reau at Washington. The Second International Sanitary nvention, held in Washington in 1905, assumed a more mal character than the previous one and resulted in the scription to a "sanitary convention ad referendum,' hich codified all the measures destined to guard the public alth against the invasion and propagation of yellow fever, ague, and cholera. This sanitary convention ad ferendum has been ratified by at least nine republics, and t is provided that the governments which have not signed e present convention are to be admitted to adherence ereto upon demand. The subjects which will especially gage the attention of the third sanitary conference have ready been suggested by the Third International Convention of American States held at Rio de Janeiro in 1895. One of them is the establishment and organisation in the ace in South America which the conference may esignate of a Bureau of Sanitary Information which will rnish to the International Sanitary Bureau already existing e necessary data to comply with recommendations relative o sanitary police. The city of Montevideo is designated as e residence of the Bureau of Sanitary Information.

National Sanitary Department for Cuba

The Provisional Government of Cuba has created a national nitary department to meet the emergencies of yellow fever. As organised it consists of a chief sanitary officer, a national nitary board, the necessary *personnel* for the office and e institutions under its control, a local sanitary officer for ch municipality, and the necessary employees. The department is created because the municipal governments have not en able to provide sufficient funds for the support of an cient sanitary service, nor has there been that concert of tion of the municipal authorities so necessary for efficient rk during the prevalence of an epidemic. There is no ubt that this nationalized sanitary service will prove of the greatest importance to Cuba, not only in protecting it from yellow fever but in improving the public health of the entire Republic.

Sept. 16th.

Medical News.

UNIVERSITY OF OXFORD.—The following degrees in medicine have been conferred:—

Bachelor of Medicine and Surgery.—John Wallace, Exeter; Richard Evans, Jesus; Cuthbert Taunton Raikes, Trinity; Ernest Laurence Kennaway, New College, Edward Alfred Cockayne, Balliol, Wilfrid Wood Wells, Merton, Arthur Salusbury MacNalty, non-collegiate; and Otto Gustav Ferdinand Lubn, Christ Church.

At examinations held recently the following candidates were successful:—

FIRST M.B. EXAMINATION.

Organic Chemistry.—E. G. Beaumont, University; C. H. Budd, Oriel, W. Burridge, Christ Church; F. A. Hampton, New College, A. H. Southam, Christ Church; A. B. Thompson, New College, C. W. Wheeler-Bennett, Christ Church, and J. A. Wood, University.

Materia Medica.—H. C. Barett, Wadham; C. F. Beevor, B.A., Magdalen, W. Burridge, Christ Church, C. B. Fenwick, Magdalen, A. D. Gardner, B.A., University; P. L. Gibson, Trinity, H. M. C. Green, B.A., Wadham; N. P. Hallows, Keble, C. H. L. Harper, Wadham, S. Hibbert, University, G. W. Johnson, B.A., Brasenose; E. G. Martin, B.A., New College; H. G. Morris, University, E. O'Connor, M.A., Lincoln, R. C. Ozanne, Hertford, J. F. Penson, non-collegiate, A. F. S. Sladden, B.A., Jesus, E. H. Udell, Queen's, G. H. Varley, B.A., St. John's, and W. E. Waller, University.

Anatomy and Physiology.—J. L. Birley, University, R. F. B. Bowes, B.A., Queen's, R. F. Bridges, B.A., University, A. R. Chavasse, Hertford, G. H. Cross, B.A., Balliol, D. C. Dobell, B.A., Christ Church, P. H. C. Fowell, B.A., St. John's, N. Glover, B.A., Trinity, G. J. Z. Jessel, B.A., University, C. Newcomb, B.A., St. John's, W. J. Oliver, Oriel, A. S. Roe, Balliol, H. W. Scott-Wilson, Queen's, C. J. G. Taylor, University, W. W. Wagstaffe, New College, and R. C. Wingfield, Trinity.

SECOND M.B. EXAMINATION.

Pathology.—C. D. H. Corbett, B.A., University, E. P. Cumberbatch, B.A., Keble, G. B. Girdlestone, B.A., New College, B. G. Klein, B.A., Corpus Christi, S. S. Strahan, Keble, J. Wallace, B.A., Exeter, W. W. Wells, B.A., Merton, and W. C. Wigan, B.A., St. John's.

Forensic Medicine and Hygiene.—M. B. Barnes, B.A., Exeter, C. G. Douglas, B.A., Magdalen, M. W. Flack, B.A., Keble, S. Horsill, B.A., New College, J. F. Hornsey, B.A., Wadham, B. G. Klein, B.A., Corpus Christi, O. G. F. Lubn, B.A., Christ Church, J. Wallace, B.A., Exeter, and W. W. Wells, B.A., Merton.

Medicine, Surgery, and Midwifery.—H. B. Billups, M.A., Worcester, E. A. Cockayne, B.A., Balliol, R. Evans, M.A., Jesus, N. Glover, B.A., Exeter, E. L. Kennaway, B.A., New College, O. G. F. Lubn, B.A., Christ Church, A. S. MacNalty, B.A., non-collegiate, C. T. Raikes, B.A., Trinity, and W. W. Wells, B.A., Merton.

M.CH. EXAMINATION.

E. Warren, D.M., New College.

FINAL HONOURS EXAMINATION, SCHOOL OF NATURAL SCIENCE.

Physiology.—Class I.—H. J. B. Fry, Magdalen, H. P. Newsholme, Balliol; E. L. Pearce-Gould, Christ Church, and E. W. M. H. Phillips, Jesus. Class II.—P. P. W. Andrews, University, G. W. Carte, New College, W. F. Harvey, Balliol; G. E. Nelligan, Exeter, and R. O. Ward, Queen's. Class III.—C. W. Armstrong, Jesus, A. Booth, Keble, A. W. Donaldson, Hertford; and W. J. Pearson, University. Class IV.—T. B. Batchelor, University.

PRELIMINARY EXAMINATION IN NATURAL SCIENCE.

Mechanics and Physics.—S. M. Bose, Worcester, R. Dell, non-collegiate, A. W. Dennis, Keble, D. D. Drury, New College, R. J. Ford, Queen's, G. P. Furneaux and R. L. Gillingham, non-collegiate, H. S. H. Guinness, Balliol, H. L. Harvey, Oriel, O. Le P. T. Heslop, non-collegiate, H. Jervis, Trinity, P. C. Lacaita, Balliol, J. T. Lattey, Christ Church; M. M. Machava, St. John's, J. D. Mackworth, Corpus Christi, F. A. Mason, St. John's, H. W. Normanton, Merton, A. G. Ogilvie, Magdalen, L. A. B. Sharpe, E. A. Sitzler, and T. O. Thompson, St. John's, F. M. Trefusis, Exeter, R. B. Turbutt, Christ Church, B. H. Walker, Queen's, G. E. Webb, non-collegiate; G. E. Whitfeld, New College, W. J. Wiltshire, Pembroke; R. B. Winser, Corpus Christi, H. S. Wreford-Glanvill, Merton, W. H. Wyatt, Exeter; and J. V. Young, St. John's.

Physics.—J. V. Collier, Christ Church; R. C. Fairbairn, Exeter; A. Jackson, Queen's, A. Juett, Brasenose, E. W. P. Newman and J. N. Oliphant, Christ Church, M. O. Raven, Trinity; and L. Pees, non-collegiate.

Chemistry.—W. H. D. Acland, Christ Church, G. H. Allington and O. Barkan, Trinity, E. Benskin, St. John's, A. C. Brandon, Merton, J. V. Collier, Christ Church, G. Cranstoun, Oriel, A. A. M. Davies, University, R. Dell, non-collegiate, D. D. Drury, New College, R. C. Fairbairn, Exeter, R. J. Ford, Queen's, G. P. Furneaux and R. L. Gillingham, non-collegiate, H. S. H. Guinness, Balliol, S. D. Gurney, Wadham, D. B. L. Hallett, University, M. R. Hely Hutchinson and J. S. Huxley, Balliol, H. Jervis, Trinity, J. L. Kathju, Exeter, J. T. Lattey, Christ Church, M. M. Machava, St. John's, J. D. Mackworth, Corpus Christi; F. A. Mason, St. John's, E. E. Mather, Exeter, P. L. Meadon, St. John's, Hon. P. A. Methuen, New College, E. W. P. Newman, Christ Church, H. W. Normanton, Merton; A. G.

certain teachers in these subjects from the Medical School to othe centres of the University, namely, University College and King's College; and (3) the guarantee on the part of this board of the payment of £500 per annum for three years to the University chest. The board were given to understand that the University had decided definitely to adopt the policy of the concentration of the preliminary and intermediate studies and that in the near future a further centre for instruction in these subjects would be erected in the immediate neighbourhood of the Imperial Institute; for without this centre there could be no effective concentration, inasmuch as University College and King's College did not meet the requirements of other schools. The representatives of the board pointed out to the delegates of the University that the transference of their students to University College and King's College must act to the detriment of their school and diminish the number of students entering each year, until this third centre had been erected; but they agreed to sacrifice their own immediate interests and adopted the agreement of July, 1905 referred to above, as they felt so strongly that the policy of the University was the right one, and the one most calculated to assist medical education in London and to attract students to the metropolis. They entered into this agreement, however, on the distinct understanding that a third centre of instruction would be erected in the immediate neighbourhood of the Imperial Institute within a few years. They were informed that such a scheme was the settled policy of the Senate of the University, that it had been approved *nemine contradicente* by the Medical Faculty, that an appeal had been issued soliciting funds for such an institute, that His Majesty the King had expressed approval of the scheme and had graciously subscribed to the appeal, that His Royal Highness the Prince of Wales had referred to the matter in terms of appreciation, and that King Edward's Hospital Fund had expressed satisfaction on the ground that such concentration would put an end to the practice of the funds of the charitable public, which were subscribed for hospital purposes, being diverted to the purposes of medical education.

The board is of opinion that any departure from the settled policy of the University in the matter of the erection of a third centre in the immediate neighbourhood of the Imperial Institute would be a grave breach of the contract entered into between the University and this hospital, and they feel assured that the Senate will refuse, when all facts are considered, to countenance any such breach of faith.

I am, Sir, your obedient servant,
(Signed) A. William West, Treasurer.

⁂ Our opinion on the question is well known. We believe that the abandonment of the Kensington centre for instruction in preliminary studies is a retrograde movement, and we trust that the Senate of the University of London may yet take this view.—Ed. L.

NOTES OF A CASE IN WHICH GLYCOSURIA, DEPENDING UPON CHOLECYSTITIS AND CHOLANGITIS, DISAPPEARED AFTER DRAINAGE OF THE BILE-DUCTS.

To the Editors of The Lancet.

Sirs,—Mr. W. Gifford Nash has very kindly written to me to say that he has also had a case of glycosuria which was cured by removal of a gall-stone. This was published in The Lancet, Nov. 1st, 1902, p. 1192. I very much regret that I had overlooked it.

I am obliged to Mr. A. W. Mayo Robson for his suggested correction of the title I gave the notes. The same idea had presented itself to me, but I was afraid the title would occupy more space than the notes themselves. I am sorry to say that, in spite of Mr. Mayo Robson's advocacy, glycosuria not only has been hitherto, but is still, regarded as a bar to operation by nearly all those with whom I have spoken upon the subject.

I am, Sirs, yours faithfully,
Wimpole-street, W., July 1st, 1907. C. Mansell Moullin.

INSURANCE AGAINST SICKNESS.

To the Editors of The Lancet.

Sirs,—Like everything that comes from his pen my excellent friend Dr. J. G. Glover's letter on the Workmen's Compensation Act does honour both to his head and heart. His feelings towards those who minister to his daily comfort show his splendidly benevolent spirit, while his appeal to the insurance associations to cast their net wider in these days of fierce competition between the different companies, from the point of view of business, is almost certain to succeed. May I venture to suggest one other risk which I have long thought it a pity has not been taken up by insurance offices. I refer to a provision against the chance of insanity, in the shape of an annuity to the insurer when that deplorable event takes place. All the statistics are ready at hand and the only difficulty would lie in estimating with sufficient accuracy the necessary loading of the particular "life" against hereditary tendencies. Take as an example: Suppose an individual with a clean history wished to insure £100 a year in the event of his becoming insane. Suppose, further, he becomes a lunatic and lives in that state of mental aberration for 30 years. The chance of his becoming chargeable is, we know, about 1 in 300. 300 individual guineas would leave an ample profit to the insuring company who had to pay the £100 yearly. And these figures do not take into account that the insurer would not at once become chargeable on the company's funds, but most likely if he began early would have made many payments before he had the misfortune to lose his reason.

Surely, Sirs, of all the ills of life nothing can be worse than for a man or woman in good position, by no fault of his or hers, to have to submit to be cared for by public, or even by private, charity. I have had the lamentable experience of shaking hands with a poor lunatic college class-fellow fallen so low as to be herded with paupers. Alas! the pity of it! I have, too, good reasons for not subscribing my name. I enclose my card, and am, Sirs, yours,

A Warm Friend of the Insane and the Helpless.
July 2nd, 1907.

THE NEW VACCINATION ORDER.

To the Editors of The Lancet.

Sirs,—Your correspondent "Another Public Vaccinator" in your issue of June 29th, p. 1806, asks, "What are the best steps to take to induce the various boards of guardians to grant us a reasonable fee for the services we are called upon to render?" One step is obvious; that all public vaccinators should procure from the Association of Public Vaccinators (the secretary's address is 1, Mitre-court Buildings, Temple, London, E.C.) copies of the article lately issued in your columns, which you have kindly allowed the association to reprint, and of the memorandum issued last week by that association. Copies can be obtained by public vaccinators at cost price and a copy of each document should be sent to every member of every board of guardians; a few shillings would supply each public vaccinator with the necessary copies, if he will take the trouble to address the envelope to the individual guardians. May I be allowed to urge public vaccinators to take this trouble? At such a crisis they must look after their own interests and try to educate the local authorities. Many boards of guardians are ready to treat their officials fairly, but they are ignorant of the requirements entailed by the Vaccination Orders.

I am, Sirs, yours faithfully,
July 3rd, 1907. Hercules to the Waggoner.

NISBET'S MEDICAL DIRECTORY.

To the Editors of The Lancet.

Sirs,—May I through your valuable journal ask those medical men who have not returned the circulars issued for this directory to do so, as it will be a matter of regret for all concerned if the information desired arrives too late for insertion. I am, Sirs, yours faithfully,

The Editor of Nisbet's Medical Directory.
21, Berners-street, W., July 3rd, 1907.

Missionary Hospital in Persia.—Major C. Ducat, H.M. Consul at Kerman, states in his annual report that the hospital of the Church Missionary Society continues to do good work and is outgrowing its present quarters. The late Governor made a grant of land as a site for a new hospital, but the grant is subject to the confirmation of the Persian Government, which has been applied for. Major Ducat adds: "What proper medical advice means in this country is shown by the fact that the news of the coming of Europeans, all of whom are taken to be doctors, spreads from village to village, and one's camp is besieged almost before it is pitched by people some of whom have come from ten to 20 miles and must have started in the middle of the night. The small European colony remains much the same as last year. The Kermanis are much less fanatical than any of the other Persians and there is no feeling of animosity to Europeans. The Khans and upper class of Persians are most friendly and a large number of the lower class either bow or wish one a respectful salaam."

Ogilvie, Magdalen; J. N. Oliphant, Christ Church; D. R. Parry-Jones, St. John's; O. G. Parry-Jones, Magdalen; Q. D. Pictor, Exeter; T. L. Price, Keble; M. O. Raven, Trinity; R. Ross, non-collegiate; L. A. B. Sharpe and E. A. Sitzler, St. John's; G. B. Tarring, Merton; T. O. Thompson, St. John's; G. E. Webb, non-collegiate; G. E. Whitfield, New College; W. J. Wiltshire, Pembroke; H. S. Wreford-Glanvill, Merton; W. H. Wyatt, Exeter; and J. V. Young, St. John's.

Zoology.—O. Barkan, Trinity; W. H. Bleaden, Brasenose; A. A. M. Davies, University; W. K. Flemmer, Trinity; G. T. Hebert, Christ Church; A. Jackson, Queen's; G. Meade-Waldo, Magdalen; W. H. Thornton, Trinity; T. A. Townsend, New College; and H. T. Vodden, Exeter.

Botany.—G. E. Beaumont, University; E. Benskin and H. M. Bond, St. John's; C. E. N. Bromehead, Merton; W. A. Cooke, Worcester; C. F. Cranswick, Exeter; V. C. H. Dearden, Wadham; A. W. Dennis, Keble; D. B. I. Hallett, University; J. S. Huxley, Balliol; A. Juett, Brasenose; N. S. Lucas, New College; J. C. Moulton, Magdalen; W. H. Ogilvie, New College; R. W. Reed and A. H. Southam, Christ Church; T. A. Townsend, New College; J. F. Venables, Magdalen; H. T. Vodden, Exeter; C. W. Wheeler-Bennett, Christ Church; S. B. White, Keble; J. A. Wood, University; and J. V. Young, St. John's.

UNIVERSITY OF DURHAM.—At examinations for the degree of Bachelor in Medicine held in September the following candidates satisfied the examiners:—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry and Physics.—First-class Honours: John Hamilton Barclay and Michael Brennan, College of Medicine, Newcastle-upon-Tyne. *Second-class Honours:* William Hudson, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Joseph Jopling Brown and Eleanor Walkinshaw, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—John Bain Alderson, Ronald Greig Badenoch, Richard Murray Barrow, Roger Errington, David Farquharson, Sarah Louisa Green; Thomas Albert Hindmarsh, Laurence Heber Warneford Iredale, Frank Hutchinson Kennedy, John Lumb, Benjamin Bell Noble, Charles O'Hagan, and Arthur Hyde Wear, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—Louis Ernest Selie Gellé, Edinburgh Medical School; Harold Llewellyn James, Guy's Hospital; and Russell Vyoyan Steele, University College, London.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—Oscar Frederick Don Airth, Isaac Bainbridge, Helen Grace Clark, Robert Vickers Clayton, Bloomfield George Henry Connolly, John Hare, Samuel Littlewood, George Cuthbert Mura M'Gonigle, and John Howard Owen, College of Medicine, Newcastle upon-Tyne; Madeline Rosa Shearburn and Matilda Ann Sinclair, London School of Medicine for Women; Eric Hemingway Shaw and Carl Johan Valfrid Swahnberg, College of Medicine, Newcastle-upon-Tyne; Olivia Nyna Walker; London School of Medicine for Women; and Stanley Worthington and James Carruthers Young, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore (University of Maryland):* Dr. Charles W. McElfresh has been appointed to the chair of Medicine.—*Bologna:* Dr. Carlo Comba has been promoted to the Ordinary Professorship of Children's Diseases.—*Chicago (Rush Medical College):* Dr. Norman M. Harris, and Dr. Horace T. Ricketts have been appointed Assistant Professors of Pathological Anatomy and Bacteriology.—*Cracow:* Dr. Alexandre Rosner has been promoted to the chair of Midwifery and Gynæcology, vacant by the death of Professor Jordan.—*Greifswald:* Dr. Paul Römer, first assistant to Professor Hess of Würzburg, has been offered the post of Director of the University Ophthalmic Clinic in succession to Dr. L. Heine who is going to Kiel.—*Lemberg:* Dr. K. Kwietnewski, formerly professor in the University of Pisa, has been appointed to the chair of Comparative Anatomy.—*Montreal (McGill College):* Dr. Armstrong has been appointed to the chair of Surgery.—*Moscow:* Dr. Alexinski has been appointed Extraordinary Professor of Surgery.—*Vienna:* Dr. Hugo Salomon has been recognised as *privat-docent* of Medicine.

DEATH OF A CENTENARIAN.—The *Times* of Sept. 18th states that Mrs. Bricknell died at Cheltenham on Sept. 16th. She was born on August 16th, 1806, and was therefore 101 years old. Mrs. Bricknell retained her faculties to the last and was present at church quite recently.

FIRE ENGINE FOR BAGNALL HOSPITAL.—The provision of fire-extinguishing appliances for hospitals is an absolute necessity in view of the helplessness of the inmates, and the governors of such institutions may be relied upon to realise their responsibilities in this connexion. The North Staffs Joint Hospital Board has just procured a Merryweather manual fire-engine for the small-pox hospital at Bagnall. This engine is suitable for use by four men and is equipped with all necessary appliances for working, including an ample supply of delivery hose. In the event of an outbreak of fire at the hospital this engine should prove very valuable.

APOTHECARIES' HALL OF IRELAND.—At a meeti of the court of directors the following were elected examin for the ensuing year:—Chemistry and Physics: Profes Hugh Ryan, D.Sc., F.R.U.I.; and J. J. A. O'Sullivr L.R.C.P. & S. Irel., D.P.H. Biology: Professor D. J. Coffe M.D., F.R.U.I.; and John Knott, M.D. Dub. Anatom Professor A. Fraser, M.D. Glasg., F.R.C.S. Irel.; and P. Fagan, F.R.C.S. Irel. Physiology: Professor D. J. Coffe M.D., F.R.U.I.; and John Knott, M.D. Dub. Medi Jurisprudence: W. Fottrell, L.R.C.P. & S. Irel.; and J. M'Walter, M.A. R.U.I., M.D. Brux., D.P.H. Pharmac J. A. Walsh, L.R.C.P. & S. Edin.; J. C. M'Walter, M. R.U.I., M.D. Brux., D.P.H.; and E. F. Hanrahan, M.I B.Ch. R.U.I. Materia Medica: John Evans, L.R.C.S. Irel and John T. D. Crinion, L.R.C.P. & S. Irel. Patholog J. F. L. Keegan, F.R.C.S. Irel.; and R. J. Rowlett M.D. Dub. Hygiene: Sir C. Cameron, C.B., M.D. R.U.I. and C. J. Powell, F.R.C.S. Irel., D.P.H. Ophthalmic Surgery: H. C. Mooney, F.R.C.S. Irel.; and F. Odevaine F.R.C.S. Irel. Medicine: John Marshall Day, M.D. Dub., D.P.H.; and John O'Donnell, M.B., B.Ch. R.U.I. Surgery (appointed by the General Medical Council): Sir Lambert Ormsby, M.D. Dub., F.R.C.S. Irel.; and Professor F. Conway Dwyer, M.D. Dub., F.R.C.S. Irel. Midwifery and Gynæcology: Gibbon Fitzgibbon, M.D. Dub.; and R. J. Fleming, M.D. Dub.

PROPOSED LABORATORIES FOR THE PREPARATION OF ANTITOXIN SERUM.—At a meeting of the Metropolitan Asylums Board on Sept. 14th a letter was read from the Local Government Board stating that it was willing to assent to the erection and fitting up of a central laboratory for the preparation of antitoxin serum and for bacteriological work, but it was advised that it would be possible to provide what was required at a less cost than £9090, for which the managers had applied for sanction, and it would not be prepared to authorise a total expenditure on the works of more than £6500. The Board was further advised that a saving of not less than £1000 might be effected if the laboratory was erected on the Balmont site at Sutton instead of at Peckham and that the balance of administrative advantage was distinctly in favour of placing the laboratory on that site. On these and other considerations the Board adhered to th suggestion as to the site made in its letter of May 2nd, and it would, therefore, not be prepared to assent to th placing of the proposed buildings at Peckham. Havin regard to these views the Asylums Board adopted a recommendation submitted by the hospitals committee agreein to the alteration of site and authorising the preparatio by the architects, Messrs. T. W. Aldwinckle and Son, of a amended scheme.

ST. BARTHOLOMEW'S HOSPITAL AND MEDICAL SCHOOL.—During the past year the following changes hav taken place in the teaching staff: Dr. Christopher Addison who was formerly dean of Charing Cross Medical School an professor of anatomy at the University College, Sheffield has been appointed lecturer and senior demonstrator o anatomy. Mr. W. D. Harmer has resigned the assistan surgeoncy and has been appointed surgeon in charge of th department for diseases of the throat and nose. Mr F. A. Rose has been appointed assistant surgeon fo diseases of the throat and nose. Mr. G. E. Gask has been appointed assistant surgeon and teacher o clinical surgery. Dr. W. S. A. Griffith has been electe physician-accoucheur with charge of out-patients an will give part of the clinical lectures on diseases o women. Dr. H. Williamson has been elected assistan physician-accoucheur and clinical lecturer in midwifery. Dr J. A. Willett has been appointed demonstrator of midwifery Mr. C. E. West has been elected assistant aural surgeon Mr. C. Gordon-Watson has been appointed surgical registra and has resigned the demonstratorship of anatomy. Mr L. B. Rawling has been appointed demonstrator of operativ surgery. Mr. R. C. Ackland has been appointed denta surgeon and Mr. F. Coleman assistant dental surgeon. Mr R. C. Elmslie has been appointed demonstrator of patholog and Dr. H. Pritchard and Mr. H. G. Ball have been electe junior demonstrators of pathology. Dr. H. G. Adamson ha been appointed chief assistant in the department for disease of the skin. Dr. C. M. H. Howell has been elected junio demonstrator of physiology and Mr. T. S. Lukis and Mr. C. T Neve have been appointed assistant demonstrators of biology —The following awards of scholarships and prizes have bee have generally been long in use and they give to the water a smell and a taste that are simply disgusting to those unaccustomed to them. Recently, however, the Jeddah municipality has acquired a certain number of barrels mounted on wheels and drawn by camels. One of these is seen in Fig. 33. They are a vast improvement on the old skins and petroleum tins. Similar barrels are in use at Aden for the distribution of distilled water.

In endeavouring to find a permanent remedy for the present unsatisfactory state of the water question in Jeddah it was necessary to bear in mind the following considerations. Springs, cisterns, and wells could not be regarded as offering a sure and permanent solution of the difficulty. As regards spring water, it might perhaps be possible to repair the conduits and to clean the reservoirs; but the sources themselves are dependent on that most uncertain factor—the rainfall. Moreover, the conduits, if repaired, would soon be damaged again by the Bedouins or others unless (an impossible alternative) they were guarded day and night by troops for the whole of their length. The tanks or cisterns are also entirely dependent on the rainfall; they collect surface waters which necessarily contain many impurities. Some of the grosser impurities, it is true, are deposited in the small outer reservoirs, or at the bottom of the tanks themselves; but after long drought, when the water is getting low in the tanks, it becomes quite undrinkable, and even at the best it could scarcely be regarded as a safe water without being boiled, or at least filtered.

The well-water is equally objectionable. Whether artesian wells would give good results at Jeddah is a question that can scarcely be regarded as settled. The tube-wells hitherto sunk never went lower than about 80 feet; the one remaining in use is only 40 feet deep and therefore is still probably only yielding surface waters. Possibly true artesian wells, going, as many of them do, to depths of 500 or 600 yards or more, would give satisfactory results, but the cost of getting the expert labour required and the uncertainty of the result were factors to be considered.

Finally, the best solution of the difficulty appeared to be the provision of distilled water, prepared in large condensers, and my recommendation to this effect has been adopted. The putting up of condensers of necessity involves a considerable initial outlay, but fortunately a way of overcoming this difficulty was at hand. During the past year a public subscription was raised, under the auspices of the Sultan, for the repair of the conduits bringing water to Mecca. Such repair was, I believe, very necessary, but according to local information the situation at Jeddah was a far more urgent one than at Mecca. At the latter the quantity of water had somewhat diminished, while its quality was said to be excellent. But at Jeddah there was neither quantity nor quality; the town was threatened with an actual water famine and was reduced to drinking water of the most unpleasant and dangerous character. So bad, indeed, had it become that the few foreign residents were reduced to the highly precarious resource of obtaining their water from ships calling at the port. The further recommendation to extend the object of the public subscription so as to include the water-supply of Jeddah with that of Mecca has been acted on, and it is hoped that the sum realised will suffice to cover both.

Though costly in the first instance, the putting up of condensers should in the long run prove a very remunerative measure. A large condenser costs some £4000. That at Oamaran (mentioned in an earlier article) cost 98,582 francs, including mounting and accessories; two of the Aden distillers cost just under £4000 each. Each of the latter produces about 55 tons of water daily, the former about 60. The Oamaran machine burns about 45 kilogrammes of Cardiff coal per ton of water produced; those at Aden about 42 kilogrammes. The staff required need consist only of one European engineer at about £30 a month, and a certain number of native stokers and labourers. At Aden the pay of the staff for running two machines is about £65 a month. If two machines were put up at Jeddah it is probable that they would not work night and day; their total output would, perhaps, be about 80 tons a day, of which (say) 20 tons would be given to officials and 60 tons sold. The total expense, including the cost of coal, pay of staff, repairs, &c., should not exceed some £250 (P.30,000) a month. If the water were sold at the exceedingly low figure of 5*s.* (P.30) a ton it would suffice to sell 1000 tons a month, or 33 tons a day, to cover the cost. The sale of 60 tons a day would produce a clear profit of 27 tons, or, at 5*s.* the ton, £6 15*s.* a day. The total annual profit would be nearly £2500 a year. In practice, however, it is to be feared that this rosy prospect will not be fully realised, from the beginning at any rate. Vested interests are extremely strong; the owners of tanks will do all they can to prevent the sale of distilled water, if they do not actually attack the machines. The people themselves, strongly conservative by nature, will take time to get accustomed to distilled water in place of the other waters they have been used to drinking. In time, however, there should be no question of the distiller or distillers, under proper management, yielding a handsome annual profit. This aspect of the question is, however, in truth, one of secondary importance in comparison with the real necessity, on sanitary and humanitarian grounds, of providing Jeddah with a certain, abundant, and safe water-supply.

(To be continued.)

MANCHESTER.

(*FROM OUR OWN CORRESPONDENT.*)

Degree Day at the University.

SATURDAY last, June 29th, which marked the end of the academic year, was also marked by the conferring of degrees at the University of Manchester. It was a remarkable fact, for this summer and for Manchester, that the day was fine, and as it was very much a ladies' day the scene in Whitworth Hall was a brilliant one. There was among the recipients of degrees a large proportion of lady Masters of Arts and Bachelors of Arts. Of 44 Bachelors of Arts taking the ordinary degree 30 were women and of the ordinary Bachelors of Science one-third were women. Illness, unhappily, did not allow of the presence of the Chancellor, the Duke of Devonshire. The degrees of Doctor of Laws and Doctor of Science respectively were conferred on Baron Kikuchi, late Minister of Education in Japan, and Dr. Hales, the eminent American astronomer and professor of astrophysics in the University of Chicago. The other degrees were then conferred. It is somewhat interesting to note that the D.Sc. and M.D. degrees, four and five in number respectively, were bestowed on men only, while the other degrees were bestowed on both men and women. In zoology the one candidate was a lady and in botany the five candidates were ladies. In the annual statement circulated by Dr. Hopkinson, the Vice-Chancellor, the number of students in the various faculties of the University was stated as follows: All faculties except medicine and technology (including 262 women students), 906; faculty of medicine (including 14 women students), 325; and faculty of technology (including three women students), 167; 50 students entered both for science and medicine. In addition to these there were 228 persons attending evening classes, 115 attending lectures on railway economics, and about 200 attending courses of lectures on law and economics at the Bankers' Institute. This very insufficient statement is enough to show the activity prevailing in the University and the influence which it is destined to exercise over the wide area from which its alumni are drawn.

Unsound Meat.

As long as there are rogues it may be taken for granted that attempts will be made to sell bad meat for good and to induce people to eat all kinds of abominable and unwholesome stuff. It is well, therefore, that the markets committee of the Manchester corporation affords some protection to the public against the slink butchers and others of like mind. The need for this protection is shown by the following facts. During the four weeks ending on May 25th last, 17,820 pounds of meat were condemned in the abattoir and carcass market, 399 pounds in private slaughter-houses, 32 pounds in the Rusholme abattoir, 20 pounds in the triperies, and 14,153 pounds in the fish markets. Rabbits, black game, ducks, hares, and vegetables were also condemned in some few cases. During the month the inspectors made 1212 visits to the meat, fish, fruit, and provision shops in the poorer parts of the city.

Rotten Grain and the Chickens.

The law, it appears, allows of spoiled or rotten grain being used for feeding our domestic fowls, if not for our own feeding. The Manchester port sanitary authority has from time to time condemned a small percentage of the ing the year 1906-07; Lawrence scholarship, G. T. and J. O. Mead (equal); Brackenbury medical ship, E. A. Cockayne; Brackenbury surgical scholar p, P. L. Giuseppi; Matthews Duncan Prize, R. B. S. ; Kirkes scholarship and gold medal, G. T. Burke; lham prize, P. L. Giuseppi; Bentley prize, H. J. Oates; kens prize, S. Dixon; Wix prize, A. W. J. Cunningham; ior scholarship, A. P. Fry; Junior scholarship, R. G. l, O. D. Kerr, and J. W. Trevan (equal); Sir George rows prize, A. W. G. Woodforde; Skynner prize, L. Giuseppi; Harvey prize, K. Bremer; Treasurer's es, R. G. Hill; Foster prize, W. O. Dale; and Shuter olarship, R. R. Armstrong.

A HOLIDAY course of hygiene for teachers in ondary schools will be held at Göttingen under the super on of E. von Esmarch from Oct. 7th to 12th. The pro mme is as follows:—First day, morning—introduction, s and methods, air and water; afternoon—visit to the works and electric power stations. Second day, morning hygiene of the school building, heating; afternoon—visit the Physics Institute. Third day, morning—ventilation, hting, seating; afternoon—visits to the gymnasium and primary school. Fourth day, morning—hygiene of the ching staff and of instruction; afternoon—visit to the ls' high school. Fifth day, morning—causes, diagnosis, l prevention of school diseases; afternoon—practical monstration of disinfection, visits to the university nasium and the town baths. Sixth day, morning—visit Cassel and inspection of hygienic appliances there.

MEDICAL SICKNESS, ANNUITY, AND LIFE SURANCE SOCIETY.—The usual monthly meeting of the ecutive committee of this society was held at 6, therine street, Strand, London, W.C. There were pre t: Dr. F. de Havilland Hall (in the chair), Dr. F. S. lmer, Dr. H. A. Sansom, Dr. J. W. Hunt, Dr. M. Green ood, Dr. W. Knowsley Sibley, Dr. F. J. Allan, Dr. St Clair Shadwell, Mr. H. P. Symonds, Mr. J. Brindley James, and r. J. B. Ball. The accounts presented showed that during e first eight months of this year the operations of the ciety had been greater than in any similar period of its orking. Since Jan. 1st last nearly £9000 had been dis ributed to the members in the shape of weekly sick pay and od cash bonuses had been given to those who reached the ifying age of 65 years; yet the funds, which now amounted o over £200,000, had received a substantial increase, as the nual income of the society was considerably larger than its tgo. Prospectuses and all particulars can be had on appli tion to Mr. F. Addiscott, secretary, 33, Chancery-lane, ndon, W.C.

GROCERY AND ALLIED TRADES ANNUAL EXHIBI TION.—The annual exhibition of the grocery and allied ades was opened in the Agricultural Hall, Islington, on pt. 23rd. The exhibition was a very large and compre nsive one and of course presented several points of terest from a medical standpoint. The food exhibits ere on a large scale and comprised almost everything the tinned-food line. The bakery exhibit was a really markable one and showed in a most instructive anner the great progress that has been made in e baker's art. Machinery has to a large extent placed manual labour in the manufacture of bread, least in the big bakeries, with probably corresponding antages to the consumer from the sanitary point of view. e Wilts United Dairies Co., Limited, manufacturers of densed milk, afforded a practical demonstration of the tire process which milk goes through before it is placed tins and retailed as condensed milk. Up to a recent iod the British condensed milk trade was wholly in the ds of foreigners, and whatever may be the opinion ld as to the merits of condensed milk as a food for ldren it is satisfactory to know that English makers are pable of turning out a product equal to that of foreign ufacturers. Amongst other exhibits of interest may be ntioned those of the Vinolia Company; Field, soap, &c.; rs' soap, &c.; Caley, chocolate, &c.; Bendorf's Cocoa; mon Co.; and J. A. Sharwood and Co., crystallised fruit. novel exhibit shown by this last-named company con ted of flowers beautifully made in crystallised sugar. e South African Food Products Co. had an exhibit ilar to that shown in the Horticultural Hall, con g of preserved fruits and wines, berry wax, and ish pipes. Horlick and Co., makers of malted milk, a good display. Brand and Co. showed samples of all their well-known products. Armour and Co. had a good exhibit. In fact, all the large firms in any way connected with the grocery and allied trades were showing at the Agricultural Hall, but lack of space forbids a more lengthy account of a very full and instructive exhibition.

BRISTOL MEDICAL SCHOOL.—The annual distribution of prizes in connexion with the Faculty of Medicine of University College, Bristol, will take place in the large hall of the College on Oct. 1st. The prizes will be distributed by Professor Francis Gotch, of the University of Oxford. The annual dinner of the Bristol Medical School, at which Mr. J. H. Parsons, F.R.C.S. Eng., will preside, will take place on the same evening at the Royal Hotel, College Green.

LONDON MEDICAL EXHIBITION.—The Third London Medical Exhibition will be held in the new hall of the Royal Horticultural Society, Vincent-square, Westminster, from Oct. 7th to 11th, from 11 A.M. to 7 P.M. daily. The promoters are putting forth efforts to make the forthcoming exhibition an even more decided success than in previous years. It is understood that the number of exhibitors this year will considerably exceed that of last year. The secretary is sending free tickets of admission to every medical man within a 20-mile radius of London. Application should be made to *The British and Colonial Druggist* offices, 44, Bishopsgate Without, E.C.

VACCINATION FEES IN ESSEX.—At a meeting of the Maldon (Essex) guardians held on Sept. 11th it was stated that the public vaccinators agreed to the new scale of fees so far as the fee of 2*s*. 6*d*. for each case performed at the same house within 24 hours after the first case, but they declined to agree to the alteration in the mileage from 5*s*. to 4*s*. for the first two miles, from 7*s*. 6*d*. to 6*s*. 6*d*. for between two and four miles, and from 10*s*. to 8*s*. 6*d*. after four miles. The matter was referred to the Local Government Board.

ROYAL SOCIETY OF MEDICINE.—The first meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine will be held on Thursday, Oct. 10th, at 7.45 P.M. As the agenda shows, this meeting should prove exceptionally interesting. There will be some business connected with the formation of the section, and the paper of the evening, will be on the Physiological Action of the Placenta, by Professor W. E. Dixon and Dr. F. E. Taylor. Future meetings of the section will be held on the second Thursday in each month (except August and September) at 7.45 P.M. Additional meetings may be held from time to time and they will be specially announced.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—On Sept. 21st at Goleen, Co. Cork, the inhabitants of the village presented a wedding gift to Mr. T. Neville, L.R.C.P. & S. Edin., and Mrs. Neville, which took the form of a suite of hall furniture of carved oak, consisting of hall-stand, table, settee, chairs, hall-lamp, hall-clock, and pictures, the latter being views of Dorset chosen to remind Mrs. Neville of her native England. Mrs. Neville is greatly respected by the inhabitants of Goleen and especially by the poor.—Mr. Thomas Gilbert Prosser, M.R.C.S. Eng., L.S.A., J.P., of Monmouth, who for 20 years has been civil surgeon in charge of the Royal Monmouthshire Engineers (Militia), has been presented with a silver coffee service and salver, suitably inscribed, by the past and present officers of the regiment.

DONATIONS AND BEQUESTS.—The late Mr. Samuel Vallentine has bequeathed £1000 to each of the following hospitals for the purpose of endowing a "Jacob and Rachel Vallentine" bed—viz., the London Hospital, St. Peter's Hospital for the Relief of Stone, Charing Cross Hospital, King's College Hospital, Guy's Hospital, St. Thomas's Hospital, the Free Cancer Hospital, and the Metropolitan Free Hospital, Kingsland-road. Such sum as the trustees of his will shall determine has also been left to the Hospital and Home for Incurable Children, Maida Vale, for a "Jacob and Rachel Vallentine" cot.—Under the will of Mr. S. Odames of Leicester £2000 are bequeathed for the endowment of four cots in the Leicester Children's Hospital, £1000 for providing a dispensary, and a like sum to found a cripples' guild.—An anonymous benefactor has promised a donation of £1000 to enable the committee of the Infants' Hospital to begin its work at the new premises, Vincent-square, Westminster, free from debt.—The Royal Dental Hospital of London has received £250, less legacy duty, from the executors of the will of the late Mr. J. L. Toole.

St. Andrew's Ambulance Association.

The annual report of this association shows that during the past year 7874 calls have been made on the wagons of the association, the total number of patients conveyed since its formation being now 85,150. In Glasgow alone the number of calls was 5195, representing an average of 14·23 turns out daily. Of these, 3155 were to accidents and 2040 to cases of illness. Lord Blythswood has accepted the honorary presidentship of the association in place of the Marquis of Breadalbane, recently resigned.

Death by Lightning.

During the thunderstorm last Saturday a distressing fatality by lightning occurred on Lethamhill golf links in the neighbourhood of Glasgow. At the time of the occurrence the weather was dry, and though the sky was lowering there was nothing to indicate the near approach of thunder. The unfortunate player was in the act of playing a mashie shot when there was a vivid flash of lightning which struck him. The lightning passed through his body, making a hole as if caused by a bullet in his head. The hair of the right side of the head and moustache was burned, and blue marks, by which the course of the current could be traced, were noticeable on the inside of the left thigh, the left knee, and both feet. The clothing was reduced to longitudinal shreds, buttons were detached from some of the garments, the soles were torn from the boots, and the works of a watch which he carried were shattered, although the gun-metal case was not affected. The lightning made a hole in the ground about six feet square and one foot deep. The club along which presumably the current travelled was undamaged. The unfortunate man's partner, who was standing some yards away, was thrown heavily to the ground but escaped with the shock.

Bacteriological Investigations in Cerebro-spinal Fever.

An interesting report has just been issued by Dr. R. M. Buchanan, bacteriologist to the city of Glasgow, in connexion with cerebro-spinal meningitis. For some time past cerebro-spinal fever "contacts" have been subjected to a systematic examination for evidence of the meningococcus, and for this purpose swabs have been taken of the secretion of the naso-pharynx. The principal difficulty has hitherto been that in the throat there exist several organisms closely resembling the meningococcus, but Dr. Buchanan believes that he has now obtained a nutrient medium which serves to demonstrate the organism in the throats of a certain proportion of patients and "contacts" within two to three days. During the month of May eight cases of cerebro-spinal meningitis came under bacteriological investigation for verification of the diagnosis, and in seven of these the meningococcus was demonstrated. The "contacts" examined during the month numbered 81, representing 20 families. In 12 of these families an organism was found in the throat, which had all the microscopical and cultural characters of the meningococcus. In five of the families it was found in one individual, in six of the families in two individuals, and in one family in three individuals—giving 20 positive results in the 81 "contacts." These results have principally been got in adults. In addition, the naso-pharyngeal secretion of seven patients and four convalescents—all verified cases—was examined. The meningococcus was found in three of the patients on the twenty-third, twenty-sixth, and sixty-first days of illness respectively, and in all the convalescents on the seventeenth, thirty-fifth, fifty-sixth, and seventy-fifth day from the onset of their respective illnesses. These results serve to indicate that the disease may be carried and spread by individuals who offer no evidence of its presence and that it may remain for a long time in the throats of individuals who are recovering from the disease.

Medical Appointments in Glasgow.

Dr. W. R. Jack has been appointed an assistant physician to the Western Infirmary. Dr. Ivy McKenzie has been appointed lecturer on medicine in the Western Medical School in place of Dr. John M. Cowan who has gone to Anderson's Medical College as professor of medicine.

Legacies to Blairgowrie Institutions.

By the death of Mr. John Scott of Blairgowrie the Blairgowrie and Rattray Districts Cottage Hospitals have benefited to the extent of £1000.

The late Dr. George Yeaman.

Glasgow has lost one of its oldest and most highly respected practitioners in the person of Dr. George Yeaman, who died at his son's residence in Hanley on June 19th. Dr. Yeaman took his M.D. at the University of Glasgow in 1854 and had a long and honourable professional career, having at one time held the posts of assistant physician to the lying-in hospital and physician to the Dispensary for Diseases of Women and Children.

Forfarshire Medical Association.

At the annual meeting of this association, Dr. W. J. Dewar, the President, being in the chair, the following were elected office-bearers for the ensuing year:—President: Dr. A. Key (Montrose). Vice-Presidents: Dr. D. Paton (Carnoustie), Dr. J. Rorie (Dundee), Dr. J. A. Dewar (Arbroath), and Mr. P. Steven (Dundee). Secretary: Dr. J. W. Miller (Dundee). Treasurer: Dr. W. E. Foggie (Dundee). The retiring President gave a lecture on Midwifery and General Practice. Next year will be the jubilee of the association and the meeting will be held in Dundee.

Resignation of the Medical Officer of Health of Stornoway.

At a meeting of the Lewis district committee the resignation of Dr. Charles M. Macrae, medical officer of health of the parishes of Stornoway, Lochs, and Uig, was considered and accepted with regret. Dr. Macrae has been connected with public health matters in Lewis for a period of almost half a century. A committee was appointed to draw up a minute expressing the appreciation of his long and valuable services and the clerk was instructed to forward a copy to Dr. Macrae. Dr. W. Bruce, county medical officer of health, Dingwall, was appointed to the vacancies.

Aberdeen Deaf and Dumb Institution: Annual Report.

The annual report for the above institution for the year 1906 shows that at Nov. 30th, 1905, the beginning of the financial year, there were 25 scholars and at the end 20. Eight children left during the year, their education having been finished, and three were admitted. The principal mode of instruction was by the sign and manual method, but each child was taught lip-speaking and reading and some of the children became very proficient in both. Kindergarten was also taught together with hand and eye training. Five boys were taught carpentry work, bench work, fretwork, and clay modelling with cast, and all the girls were taught drawing and painting. The Government grant for the year was £133 16*s*. 3*d*.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health Questions in Belfast.

ONE of the questions specially raised before the Belfast Health Commission was the want of knowledge on the part of the health authorities of the *locale* of disease. It appears now that the public health committee of the city has had a communication from the Local Government Board of Ireland to this effect. The Local Government Board will be prepared to receive an application from the committee that an order should be made (under Section 11 of the Public Health Act, 1878) amending the duties of the registrars who are medical officers of health, so as to include the duty of making returns to the superintendent officer of health of the deaths occurring in their respective districts. As a result on June 25th a deputation from the public health committee conferred with the Local Government Board in Dublin, other topics coming up for discussion being the proposed substitution of ashbins for ashpits and the reservation of beds for the use of the corporation in the Forster Green Consumption Hospital. The deputation, which was sympathetically received, was advised to approach the Registrar-General of Ireland, as the Local Government Board considered it was the Registrar-General's duty to demand from the local registrars a copy of all deaths registered by them. The Local Government Board said that a communication had been received from a member of the corporation objecting to the arrangement entered into with the Forster Green Hospital, which would be sent to the public health committee to consider; and as to the introduction of ashbins, while the Board was greatly in favour of more frequent removal of house refuse it recommended that a case should be submitted to counsel for his opinion and then forwarded to the Board for its consideration.—At a meeting of the public health committee held on June 27th it was reported

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Davidson, G. B., M.B., B.C. Cantab., has been appointed Medical Officer to the Post Office, No. 6 Albury District of the Guildford Union, Public Vaccinator, and Certifying Factory Surgeon

Day, W. F. L., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator for the Parndon, Nazeing, and Roydon Districts of the Epping Union.

Evans, R. E., M.D., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Newcastleton District of the county of Roxburgh.

Hilton, Albert, L.S.A., has been appointed Medical Officer of Health to the Hurst District Council, Ashton-under-Lyne.

King, D. Barty, M.D., M.R.C.P. Edin., has been appointed Examiner in Medicine and Clinical Medicine at the University of St. Andrews.

March, Geoffrey Colley, L.R.C.P. Lond., M.R.C.S., has been appointed a District Medical Officer by the Dorchester (Dorset) Board of Guardians.

Riggall, Robert Marmaduke, L.R.C.P., has been appointed Third Assistant Medical Officer to the Devon County Asylum, Exminster.

Winsley, near Bath, Three Counties (Gloucester, Som and Wilts) Sanatorium for Consumptives.—Resident Me Officer, unmarried. Salary £200, rising to £300.

Worcester County and City Asylum.—Third Assistant M Officer, unmarried. Salary £140, rising to £160, and all found.

The Chief Inspector of Factories, Home Office, S.W., gives not a vacancy as Certifying Surgeon under the Factory and W *shop Act at Portrush*, in the county of Antrim.

Births, Marriages, and Deaths.

BIRTHS.

Caley.—On Sept. 19th, at 24, Upper Berkeley-street, W., the wi H. A. Caley, M.D., F.R.C.P., of a son.

Winton.—On Sept. 21st, at Worple-road, Wimbledon, the wi W. B. Winton, M.A., M.D., of a daughter.

MARRIAGES.

Jones—Exsor.—On Sept. 17th, at St. Mary's, Prittlewell, Frank Jones, M.B., M.R.C.S., to Kathleen, younger daughter of Mr. Mrs. F. G. Exsor of Westcliff, Essex.

Travers—Kinross.—On Sept. 19th, at the Church of St. A Teddington, by the Vicar and the Rev. H. B. Eardley, M.A., Ernest Frank Travers, M.D. of St. John's, Tunbridge Wells, fifth son of the 22, Upper Phillimore-place, Kensington, and of Mrs. Travers, William Travers, M.D., F.R.C.S., to Edith Mary, only dau 2, Phillimore-gardens, Kensington, of the late John Kinross of Dundee.

DEATH

Gould.—On Sept. 22nd, at Hatherleigh, Devon, John Gould, M.R.C.S., aged 85 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Bir Marriages, and Deaths.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Practitioners' Association.

THE German Medical Practitioners' Association held its annual meeting of delegates on June 21st and 22nd at Münster in Westphalia, under the presidency of Professor Löbker of Bochum. The President, in his introductory address, pointed out that the question of sick clubs, and especially the introduction of the free-choice system, continued to be an important subject of interest for the medical profession in Germany. Although this system was making marked progress (it has recently been introduced by certain railway authorities for their employees) it still had many active adversaries. Medical men engaged at fixed salaries by sick clubs feared that they might lose a portion of their income under the free-choice system. The extension of the compulsory membership of clubs, as contemplated by the Government, would still more restrain free practice. At the present time more than one-third of the population of the German Empire belonged to sick clubs. It was said that the Government would propose to include domestic servants, agricultural labourers, and other persons earning less than 3000 marks (£150) per annum under the workmen's insurance law. Should this intention be realised, then in the Prussian province of Saxony the whole population except 4·7 per cent. would be compelled to become members of sick clubs. It was obvious that the carrying into effect of such a law was impossible without the collaboration of the medical profession. Dr. Pfalz of Düsseldorf gave an account of the existing relations between the clubs and the medical profession and refuted the arguments of the adversaries of the free-choice system, especially their assertion that the expenses were too high for the clubs. A principal point of the discussion concerned the question whether the medical men appointed at fixed salaries as medical officers to clubs should be entitled to compensation in the event of losing their present positions in consequence of the introduction of the free-choice system. A motion was finally adopted to the effect that the free-choice system ought to be introduced by law and not (as has been hitherto the case) optionally and by agreement with the clubs; that the law should contain a provision to the effect that the rights and duties of the medical men engaged in club practice must be determined by the local representatives of the profession, together with the representatives of the clubs, excluding in this way any preponderance of the club committee; that a club should not have power to dismiss a medical man but that complaints or cases of alleged misconduct must be brought before a court of arbitration; and that the medical men acting hitherto as officers of the clubs should have the income of the previous year guaranteed in the event of the introduction of the free-choice system provided that they continued their club practice under the new system. Another subject of discussion concerned the fees for certificates for private insurance companies. It was agreed that the minimum fee should be 10 marks (10*s.*). With regard to medical practice by unqualified persons, a motion was adopted to the effect that it ought to be prohibited by law.—The *Leipziger Verband*, an association of medical men modelled in some respects on the lines of a trade union and possessing a large strike fund, held its annual meeting the day before the meeting of the Practitioners' Association. Both organisations, which in the beginning were rather hostile to each other, have now joined in mutual coöperation. The members at the present time number 20,000, including thus nearly every medical man engaged in practice. The Verband has 124 sections and 1113 local delegates. It was reported that 3374 appointments and vacant practices were obtained for members by the instrumentality of the Verband. The shipping companies' union has undertaken to appoint medical officers to passenger vessels only under the conditions laid down by the Verband. Since its existence the Verband has dealt with 594 disputes between clubs and the medical profession, of which the result was favourable to the profession in 464 cases and favourable to the clubs in 16 cases, whilst in 114 the matter is not yet decided. The Verband has petitioned the War Office to prohibit army medical officers undertaking the work of civilian practitioners. The general staff-surgeon, as head of the Army Medical Corps, has replied that civil practice could not be closed to the army medical officers but that the War Office has issued an order prohibiting army medical officers from applying for civil appointments under other conditions than those approved by the local profession.

Deaths of Medical Men.

Dr. Theodor von Jürgensen, ordinary professor of medicine at Tübingen, died in that city on May 8th. He is known as one of the early promoters of hydrotherapy in Germany. As early as 1866 he recommended the treatment of enteric fever by cold baths and at a subsequent period the treatment of pneumonia by the same method. He has published many works and essays, of which the principal are an essay on the temperature of the healthy individual; on pneumonia, which as early as 1874 was regarded by him as an infectious disease; on septicæmia of obscure origin; on acute exanthemata, &c. He was born in 1840 at Flensburg in Schleswig, being the son of a medical practitioner. He received his professional education at the universities of Kiel, Breslau, and Tübingen, and after becoming qualified was appointed an assistant at the medical clinic at Kiel, where he was recognised *privat-docent* in 1864. In 1869 he became extraordinary professor at the University of Kiel and in 1873 ordinary professor at Tübingen, where he passed the remainder of his life.—The death is also reported of Dr. Litten, extraordinary professor of medicine in Berlin and chief physician to the municipal branch hospital. Professor Litten was born in 1845 and became qualified in 1870. He served in the war with France and then went for study to Vienna, Prague, London, and Edinburgh. He afterwards became an assistant to the celebrated Professor Cohnheim at Leipsic and Professor Fredrichs at Berlin. In 1897 he became chief physician to a municipal hospital. His principal work concerned the relations between accidents and internal diseases, especially pneumonia as a sequel to contusion of the thorax and traumatic endocarditis.

July 1st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The International Congress of Physical Therapeutics.

AN exceptionally strong organising committee is at work on the preparations for this Congress, the second of its kind, which will be held in Rome from the middle of October to the close of the third week of that month. Its president is the Senator Guido Baccelli, professor of clinical medicine in the Roman School, and among his assessors are Dr. Leon Bianchi (medical psychology), Naples; Dr. Camillo Bozzolo (institutes of medicine), Turin; Dr. Antonio Cardarelli (clinical medicine), Naples; Dr. Achille De Giovanni (clinical medicine), Padua; Dr. Enrico de Renzi (clinical medicine), Naples; Dr. Francesco Durante (clinical surgery), Rome; Dr. Pietro Grocco (theoretical and practical medicine), Florence; Dr. Eduardo Maragliano (medical pathology), Genoa; Dr. Augusto Murri (clinical medicine), Bologna; Dr. Enrico Morselli (medical psychology and therapeutics), Genoa; Dr. Gianbattista Queirolo (clinical medicine), Pisa; Dr. Eugenio Rossoni (medical pathology), Rome; Dr. Augusto Tamburini (psychiatry, systematic and clinical), Rome; and many others, among whom I may mention the professor of medical hydrology in the Roman School, Dr. Paolo Casciani. All those of the profession who give in their names to the general secretary of the Congress, Professor Carlo Colombo, No. 1, Via Plinio, Rome, inclosing an order for 20 francs as titular members (lady associates being admitted on the same conditions for 15 francs), will be entitled to a "libretto di scontrini" (book of railway tickets) enabling them to travel from one end of the Peninsula to the other at fares reduced from 40 to 60 per cent., available from Oct. 1st to Nov. 15th. This provision was devised in concert with the Minister of Public Works by the organising committee with a view of facilitating the visits of foreign members of the Congress to the various health resorts of Italy by way of enabling them to realise the resources of the kingdom in climatic stations, in "sun-traps" on the seaboard, and in balneary institutions, thermo-mineral and other. Annexed to the Congress in Rome there will be open to all members an "Esposizione Speciale di Apparecchi per Cure Fisiche, Acque Minerali, &c.," at which there will be on view all the latest appliances and apparatus in electro-therapy, photo-therapy, medical gymnastics, orthopædics, and so forth. Add to this a complete assortment of specimens of the various mineral waters known to science, "prodotti dicine. 3.30 P.M.: Mr. Cargill: Ophthalmology. EDITORIAL NOTICES.

is most important that communications relating to the orial business of THE LANCET should be addressed strictly "TO THE EDITORS," and not in any case to any tleman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

especially requested that early intelligence of local events ing a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

ures, original articles, and reports should be written on ne side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

ers, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

cannot prescribe or recommend practitioners.

al papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

ers relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

HE Index to Vol. I. of 1907, which was completed with issue of June 29th, and the Title-page to the Volume, o given in THE LANCET of July 6th.

VOLUMES AND CASES.

OLUMES for the first half of the year 1907 are now ly. Bound in cloth, gilt lettered, price 18s., carriage n.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Halifax Courier, Westminster Gazette, Daily Chronicle, Edinburgh Dispatch, Morning Post, Daily News, Yorkshire Observer, Glasgow News, Nottingham Evening News, Morning Advertiser, Glasgow Evening Times, Huddersfield Examiner, Nottingham Express, Aberdeen Daily Journal, Sunderland Echo, &c.*

Obituary.

SIR WILLIAM TENNANT GAIRDNER, K.C.B., M.D. EDIN. & DUB., LL.D. EDIN., F.R.S., F.R.C.P. EDIN. & IREL.

HONORARY PHYSICIAN-IN-ORDINARY TO H.M. THE KING IN SCOTLAND; HONORARY CONSULTING PHYSICIAN TO THE WESTERN INFIRMARY, GLASGOW; LATE PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW, ETC.

BY the death of Sir William Gairdner, which occurred somewhat suddenly on June 28th at Bracondale, Colinton, Midlothian, Scotland has lost one of the most learned and cultured exponents of medicine who taught in her schools during the past century. He had reached the ripe age of 82 years but he never ceased to take an active interest in the affairs of his profession. Thus as recently as 1902 he wrote in the *Glasgow Medical Journal* on the danger of the growing practice of prescribing opium in pneumonia, and two years later he made an interesting communication to our own columns describing a simple device by which he was able to make the most of his eyesight for reading, in spite of the fact that he had totally lost the use of one eye by a detachment of the retina ten years before and that there was a commencing cataract in the remaining eye.

William Tennant Gairdner was the son of an Edinburgh physician, Dr. John Gairdner, and was born in Edinburgh on Nov. 8th, 1824. As he was destined for the medical profession he naturally entered the university of his native town, in which he graduated M.D. in 1845, and the following year he held the post of resident medical officer at the Edinburgh Royal Infirmary; it soon became evident that he was marked out for distinction and in 1848 he was appointed pathologist to that institution. In 1850, at the early age of 26 years, he was elected a Fellow of the Royal College of Physicians of Edinburgh, which prepared the way, three years later, for his appointment as physician to the Royal Infirmary. At this time he began his teaching career, becoming the extra-mural lecturer in Edinburgh on the practice of medicine and clinical medicine. He held this post until 1862, by which time he had acquired such a reputation, both as physician and teacher, that he was invited by the University of Glasgow to accept the chair of medicine that had fallen vacant in that school owing to the resignation of Dr. John Macfarlane. He accepted the offer and remained professor of physic in Glasgow until the year 1900 and *ex-officio* physician to the Glasgow Royal Infirmary, with the result that not only the University but also the city derived the greatest benefit from his presence in their midst. He had already shown his interest in the then elementary science of public health, as was evinced by his publishing, in the year of his appointment to Glasgow, a valuable book entitled "Public Health in Relation to Air and Water," which epitomised what was then known on the subject, and he was consequently asked to undertake the onerous task of chief medical officer of health of the city of Glasgow at a time when that city was crying out for sanitary reform. He considered it his duty to accept this post, although it considerably hampered his clinical opportunities, and for ten years carried out his duties with such public-spirited zeal and efficiency that his name deserves remembrance as that of a true pioneer of sanitary reform. He had to face conditions of dirt and overcrowding such as do not exist in Great Britain to-day, and which are best exemplified by the fact that perhaps his most important contribution to clinical medicine was based on the opportunities which Glasgow gave him to study the treatment of typhus fever. He did most valuable work also in combating a severe epidemic of small-pox and, as we have indicated, his general sanitary work effected a complete change for the good in the unhealthy quarters of the city. His labours brought recognition of their merit, both within and without his University, for he was appointed an honorary physician-in-ordinary in Scotland to Queen Victoria, the present King conferring a similar honour upon him at his accession. He was also elected a Fellow of the Royal Society and, moreover, received the honorary degrees of LL D. at Edinburgh in 1883 and of M.D. at Dublin in 1887; in the same year he also received the honorary Fellowship of the Royal College of Physicians in the latter city. Other distinctions that fell to him were the Presidency of the British Medical Association in 1888 and the important task of representing the University of Glasgow in the General Medical Council from 1893 to 1903. He relinquished his chair in this University in 1900 and retired to his birthplace, Edinburgh, to spend the evening of his days. In 1889 he had received an official recognition of his public services in his creation as a K.C.B. He married in 1870 Helen Bridget Wright of Norwich, who survives him, as do his four sons and three daughters.

Sir William Gairdner will be remembered in his universities as an original thinker and as a teacher with a marked personal attraction. He appealed more especially to the thoughtful student, although he must have inspired all who knew him with an admiration for his genuine love of truth. His disregard for accepted authority until he had proved the matter for himself more than once brought on him the reproaches of his generation and his sharp conflicts with the opinions of other people when he was convinced of their error made some think that he was influenced by a personal animus against them. Nothing could be further from the case, his sole motive was an almost painfully exact sense of duty which doubtless had its origin in the deeply religious cast of mind that dominated his whole life and to which he did not fear to give public expression in the thoughtful and scholarly presidential address that he delivered before the British Medical Association in 1888, in which he was greatly concerned to demonstrate that there was no true incompatibility between a genuine personal religion and a keen appreciation of natural science; indeed, in this same address he urged the necessity of a deeper preliminary training of medical men in this subject than was at that time required. The address was published with others under the title of "The Physician as Naturalist" in the year after its delivery. Other works that he published were, "Lectures to Practitioners" (jointly with Dr. J. Coats) in 1888, in which he dealt with tabes mesenterica and urged that the disease was not necessarily so hopeless as was then believed; he also drew attention to the method of treating it by simple laparotomy and irrigation. In the same year appeared his work "On Some Modern Aspects of Insanity," and his last publication was in 1903, when his kindly philosophy crystallised out into a non-medical work entitled "The Three Things that Abide," to wit, the three great Christian virtues which he had conspicuously shown. Of his occasional contributions to the medical press we may note certain studies in heart disease, especially those dealing with angina pectoris, aortic aneurysm, and sudden death. An introductory lecture on clinical medicine delivered to his Edinburgh students at the beginning of his last course there, which was reproduced in THE LANCET of Jan. 25th, 1862, well reveals the man's mind. The utmost endeavour is apparent to combine his duty towards his students with his duty towards his patients, and he insists that a hospital ward is a sick-room before it is a class-room. He insisted always on the *vis medicatrix naturæ* and his expectant method of treatment earned him in some quarters an undeserved reputation for an intolerance of drugs. He was far too much on the side of truth to take up any such bigoted standpoint; the principle that he did oppose was that of mediævalism, of blind and unreasoning submission to academic authority. We may quote from a leading article that was written about his methods in our columns in 1864.

> Before attaining to his high position, and equally since, it has been his delight to teach others and himself not to dogmatise, but to observe, to reason, to get rid of errors, and to establish practice on a sound basis such as could be defended before men of science. ...... A feature of Dr. Gairdner's writings, which must always command respect, is his great moderation and care, both of statement and inference; the anxious way in which he qualifies conclusions which may seem favourable to his own views, or against the views and practises of others. ...... His sense of responsibility as physician to a great hospital, giving the cue to hundreds of pupils, appears in every line, as does also the sense of evidence and what constitutes proof of the virtue of medicine or any given line of treatment.

This was written *apropos* of an article contributed to THE LANCET of March 12th, 1864, which was probably the most important of Gairdner's contributions to clinical medicine, and has a somewhat apposite significance at the present day. At that time typhus fever was prevalent both in Glasgow and in London, and in accordance with a fashion that had recently been introduced to medical practice, especially in dealing with the exanthemata, it was being almost universally treated with enormous doses of alcoholic stimulants. The great apostle of this method was Dr. Todd who was running up a wine and spirit bill on behalf of his patients at King's College Hospital that was only possible in an age that knew no official inspection of hospital accounts.

found in a leading article contained in another part of our present issue, and pathologists will agree that fresh light has been thrown upon some important points. Sir William Church concluded by saying that much attention had been given during the past year to various alleged cures for cancer, but it was found impossible to ascribe a curative value to any of them. Experiments with trypsin alone, or in conjunction with amylopsin or as pancreatic extract, had been made, and it appeared in mice to exert no effect on the growth of the tumours. He also called attention to the efficient manner in which the superintendent and his assistants, Dr. Murray, Dr. Haaland, and Mr. Bowen, had carried on the work of the research, and to the assistance received from Dr. S. Monckton Copeman and Dr. Hake in examining the gastric secretion of mice.

Sir HENRY SWANZY, in seconding the motion, said that the thanks of all were due to Dr. Bashford and his able assistants for the efforts which they had been making to solve the many problems connected with cancer.

The motion was carried unanimously.

Sir JULIUS WERNHER proposed a vote of thanks to the chairman and members of the executive committee, the sub-committee, the honorary treasurer, the secretary, auditor, and others who had assisted in the work of the fund during the past year. The work of the fund was in some quarters thought to be slow but there were very few people who recognised the nature of the scientific difficulties which had to be surmounted. Owing to the generosity of Mr. and Mrs. Bischoffsheim there was now a prospect of their having a sufficient income from investments to meet their normal requirements.

Mr. FLORENCE seconded the motion, which was unanimously agreed to.

Mr. MORRIS moved :—

> That the general committee desire to place on record their deep sense of gratitude to Mr. and Mrs. Bischoffsheim for their recent munificent gift of £40,000, which, together with Mr. Bischoffsheim's original donation of £5000, will do so much towards placing the Imperial Cancer Research Fund on a secure financial basis.

Sir CHARLES MORRISON BELL seconded the motion which was adopted unanimously.

On the motion of Dr. BRADFORD, seconded by Mr. LUDWIG NEUMANN, Mr. Watson Cheyne was re-elected a representative of the general committee on the executive committee; and on the motion of Mr. BUTLIN, seconded by Sir JOHN MCFADYEAN, Sir John Tweedy was elected a member of the general committee.

Sir R. DOUGLAS POWELL proposed a vote of thanks to the Prince of Wales for presiding and referred to the great interest which His Royal Highness had shown in the Research Fund from its foundation. This circumstance was a great encouragement both to the executive committee and to those officers who were engaged in research work; it was also an assurance to the public that any practical results would at the earliest moment be applied to the relief and prevention of this formidable and very prevalent disease.

Mr. EDMUND OWEN seconded the motion which was passed by acclamation.

The PRINCE OF WALES, in reply, said: It is a great pleasure to me to have been able to preside at this annual meeting of the Imperial Cancer Research Fund, and I wish to express my gratitude to Sir Douglas Powell and Mr. Owen for the kind terms in which they have proposed and seconded this vote of thanks, and to you, gentlemen, for the hearty response which you have given to it. I have been much interested in listening to Sir William Church's remarks on this year's report of the general superintendent. We have every reason to be satisfied with the growing confidence of the public in the work of the Fund. This is evident from the wide development of its investigations, in which workers in all parts of the world are now taking part; from the endeavours which are now being made in France, Belgium, Scandinavia, and the United States to organise similar investigations; and last, but not least, by the munificent donation of £40,000 from Mr. Bischoffsheim, a vice-president, and Mrs. Bischoffsheim in celebration of the happy event of their golden wedding. I am glad to have this opportunity of publicly expressing my deep appreciation of their splendid and unexpected gift. The broad lines of inquiry undertaken by the Imperial Cancer Research Fund have, we feel certain, influenced the whole nature of investigation at home and abroad. It is recognised that the work is conceived and carried out in a liberal spirit, that whatever facts are ascertained are immediately made known to everyone, that our material is freely placed at the disposal of all who are qualified to use it to good advantage, that our staff is not working for its own ends but with a whole-hearted desire to help on a solution of the problem. From the general superintendent's report we may gather that the result of the research has been to leave behind various vague issues which it was necessary to investigate in order to clear away doubts and to narrow down the issue to a certain definite line of investigation in which the clue to the nature of cancer must be sought. Although many new facts have been ascertained they do not as yet justify hopes of a new treatment. Good progress is being made in a scientific sense, which is, after all, the object of the work, and as scientific research must be sure and accurate so must it be laborious and slow. It is hoped, therefore, that the public will continue by its sympathy and financial assistance to support the work of the Imperial Cancer Research Fund and be willing to exercise the patience necessary for prolonged and systematic investigation. Compared with other diseases, cancer has, alas! such peculiar terrors of its own that impatience for the discovery of the cause and of successful treatment is only natural. But the fact that alleged cures are being submitted to impartial tests, such as the report shows to have been done in the case of trypsin, will, I hope, assure the public that everything will be done to take full advantage of any means that may be discovered to alleviate suffering. Another tribute to the success of the efforts of the fund is the number of applications from skilled investigators to take part in the work. Thanks to the liberality of the Royal Colleges, further accommodation has been placed at the disposal of the general superintendent and he has, therefore, been enabled to add materially to the staff. We have every reason to congratulate ourselves upon having secured the eminent services of Dr. Haaland who previously held the appointment of assistant of the Pathological Institute, University of Christiania. I wish to express my thanks to the chairman and members of the various committees, Dr. Bashford, and the officers of the Fund for the valuable and untiring services which they have given during the past year to the work of the Fund.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the office, 37, Soho-square, on June 28th, Mr. HENRY MORRIS, the treasurer of the College, being in the chair. Among those present were Sir William S. Church, Sir R. Douglas Powell, Sir Constantine Holman, Mr. J. Paul Bush, Dr. J. Cahill, Dr. Charles Caldecott, Dr. W. Collier, Mr. George Eastes, Mr. D. Powell Evans, Dr. Clement Godson, Mr. R. Charlton Harrison, Mr. H. W. Kiallmark, Dr. F. Needham, Mr. F. H. Short, Dr. St. Clair B. Shadwell, Dr. F. Taylor, and Dr. Nestor I. C. Tirard.

Numerous letters of regret for absence having been read the secretary announced the result of the voting for pensioners and foundation scholars, the successful candidates being as follows :—

PENSIONERS.

	Votes.
1. France, Mary	6118
2. Phillips, Thomas G.	5245
3. Hemingway, Louise	3994

FOUNDATION SCHOLARS.

	Votes.
1. Harlock, Eric D.	13,212
2. Ffrench, Desmond A.	6223
3. Beasley, Henry E.	6219
4. Barr, John W.	5342
5. Ewbank, Charles H. P.	5112
6. Wood, Arthur R.	4857
7. Bland, L. Harry F.	4731

The SECRETARY reported that as vacancies for pensionships had arisen since the voting papers were printed the council would admit at its meeting that day the two applicants heading the list of unsuccessful candidates, so that Mrs. Charlotte M. Nutt would be appointed a Pugh pensioner and Mrs. Emily Worboys would be appointed an ordinary pensioner. The annual report of the council to the governors stated that in the year 1906 there had been an improvement in the income from subscriptions, donations, and bequests as compared with the previous year, with the

Surgery, have been promoted to Extraordinary Professorships.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on June 27th, Dr. F. H. Champneys being in the chair. On the motion of Sir William Sinclair, seconded by Mr. Parker Young, the following motion was passed:—

> That inasmuch as changes in the pulse and temperature are the earliest and surest indication of the onset of puerperal fever when the disease is still amenable to treatment this Board resolves to call the attention of local supervising authorities to the importance of instructing and encouraging midwives practising within their areas in taking and recording the pulse and temperature in every case under their care.

Letters were read from the town clerk of Southampton asking the Board to rescind its resolution of censure for having given a false certificate of still-birth, passed on Jan. 31st, 1907, on Adeline Letitia Bellis, on her own admission. The Board decided that the town clerk of Southampton should be informed that the Board declined to re-open a case which had already been reconsidered at the request of the local supervising authority together with the whole of the facts as presented by it and as to which no fresh facts were suggested. The following midwives were censured: Ellen Greenwood for not having advised that medical assistance should be sent for in a case of breech presentation in a primipara; Mary Lixton for not having advised that medical assistance should be sent for in a case of ophthalmia neonatorum; and Annie Duncalf, for not having advised that medical assistance should be sent for in a case of rigor and for not having taken the temperature of the patient after the occurrence of a second rigor. The following midwives were cautioned; Jane Jones, as to the strict observance of the rules of the Board, and in particular as to those requiring her to notify to the local supervising authority in cases of still-birth, and when medical assistance has been sent for; and Mary Chalk, as to the strict observance of the rules of the Board, and in particular as to that requiring her to send for medical assistance in a case of inflammation about the navel of a child.

SOCIETY OF ARTS.—The annual general meeting of the Society of Arts, the 153rd since the foundation of the society, was held on June 26th, Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., chairman of the council of the society, being in the chair. The principal business of the meeting was the election of the council for the year and the reception of the annual report of the council. H.R.H. the Prince of Wales was re-elected President of the society, an office which His Royal Highness has filled since 1901. The report reviewed the proceedings of the society during the past session; it referred to the award of the Albert medal to Lord Cromer, and gave a list of the other medals awarded during the session. Amongst the prizes announced for next year is a gold medal under the Benjamin Shaw Trust for Industrial Hygiene, similar medals under the Stock and Mulready Trusts to students of schools of art, and one under the Fothergill Trust for the best portable apparatus for use in mines and other places where the air is noxious, enabling men to undertake rescue work. It was noted that there had been a slight increase in the number of candidates at the society's examinations, the total number of papers worked being 24,568. It was announced that a committee had been appointed to make further investigation into the subject of the deterioration of paper, on which subject a committee had reported in 1898. The election of their Majesties the King of Denmark and the King of Norway as honorary Royal members of the society on the occasion of their visit to this country was mentioned. The report concluded with a reference to the members of the society who had died during the past year, the most noticeable of whom was Sir Benjamin Baker.

THE ELEVENTH ANNUAL REPORT OF THE NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.—The excellent work which this very useful association continues to do is shown in its latest report. We learn that the "after-care" work—i.e., the placing in suitable situations and the permanent supervision of children incapable of further improvement—has been especially engaging the attention of the association during the past year, and resolutions passed at the London Conference urging the importance of this system were forwarded to the Royal Commission on the Care and Control of the Feeble-minded. The movement is obtaining the support of an increasing number of medical men whose names include many that are authoritative in this connexion. The report includes an interesting discussion on the connexion of alcoholism and feeble-mindedness which recently took place at a meeting of the association. There was a variance of opinion as to the extent of the effect that alcoholism in the parents can have in producing feeble-mindedness in the offspring, but there was a general concurrence as to the fact that parental intemperance was so frequently associated with degeneracy of offspring that it must be reckoned as a factor in producing congenital mental defect. The meeting was agreed as to the advisability of asking for legislation to prevent young children from entering public-houses. A colony and children's home is to be shortly opened but curiously its location is not mentioned in the report. Anyone desiring to give their support to the association can obtain information about it from the secretary at Denison House, 296, Vauxhall Bridge-road, London, S.W.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—The annual prize-giving to the successful students of the hospital took place on July 2nd in the board room of the hospital; Mr. Yool, in the absence of Sir John Wolfe-Barry, was in the chair, and the Right Honourable Alfred Lyttelton, K.C., M.P., distributed the prizes. Mr. Lyttelton, having first congratulated the prize-winners on their success in a few humorous words, deprecated his own personal qualifications for officiating on the interesting occasion. He suggested that it would have been more appropriate that a medical man should have addressed a gathering of distinguished men of science rather than a Member of the House of Commons and a lawyer. In a more serious vein Mr. Lyttelton pointed out how manifold were the gifts required by medical men outside intellectual attainments and that in forming an opinion on a medical case in which all the circumstances were not known and sometimes the truth was wilfully perverted genius was required. He advised his hearers to develop the feminine quality of intuition. In dealing with a patient also they must distinguish between philosophic methods of thought and the methods of action which in this instance were called for. No doubt, even though it crossed their mind, must be apparent to the patient but they must give their advice with authority and confidence. Two very necessary qualities in the medical man were patience and a cheerful tenacity. Though he was of opinion that athletics were at present overdone it was unwise to neglect them altogether in this age of stress when variety was required for recuperation of nerve powers. He also drew attention to the importance of discussion of medical topics among medical students and pointed out how by this means half truths were found out, ignorance was exposed, and true knowledge was gained.

DURHAM COUNTY CONSUMPTION SANATORIUM: A SECOND SANATORIUM TO BE PROVIDED.—The annual meeting of the Society for the Prevention and Cure of Consumption in the County of Durham took place at the sanatorium, Stanhope, on June 29th. Mr. J. A. Hildyard presided. Dr. W. Robinson (Sunderland) moved and Councillor Elliott (Gateshead) seconded the adoption of the annual report, of which the following is a summary. The measures taken by the society and by the various sanitary authorities in the year which would tend to stop the spread of the disease were mentioned. The Lanchester rural district council is using the empty wards of its isolation hospital for consumptives with satisfactory results and Sunderland is obtaining powers to insure a tubercle-free milk-supply. Special homes for advanced cases were strongly advocated. The death-rate from tuberculosis in the county is steadily declining. The sanatorium contained 45 beds and the average daily number of patients was 43·4, each patient staying on an average 13·2 weeks and costing 17*s.* 10*d.* per week. Applications for admission numbered 257 and 176 patients were admitted and the results of treatment were considered eminently satisfactory. In seven years the applications had been about 1400 and the admissions 800. An after-care association and a working out-door colony are much needed. The income for the year was £3362 and the expenditure £1995. Local authorities subscribed £1223 and sent 79 patients, and working men subscribed (at 1*s.* per annum by each man and collected at the works) £761 and sent 38 patients. Payment by patients at various rates up to 2 guineas per week amounted to £1071 and £196 were received from private subscribers. Dr. J. Gray read his annual report and Mr. C. E. Thompson moved a proposition "that the committee be ide and 11·07 per cent. on the female side. There was no tbreak of epidemic disease during the year.

City and County of Bristol Asylum (*Annual Report for 906*).—There were 944 patients (418 males and 526 females) n the books of the asylum on Dec. 31st, 1905; of these two ales and ten females were private patients. During the year 19 patients (91 males and 128 females) were admitted and of hese four females belonged to the private class. The total umber of patients who were discharged or died during 1906 as 240 (87 males and 153 females); of these 87 (29 males nd 58 females) were "recovered," 54 (seven males and 47 emales) were "relieved," two (one of each sex) were "not mproved," and 97 (50 males and 47 females) died. The percentage of recoveries on the admissions, excluding transfers, s 41·85. The death-rate on the average number of resident atients was 10·52 (11·93 males and 9·34 females), and is ower than any year since 1901. The asylum is reported to e overcrowded and throughout the year the isolation ospital has been occupied by 20 male patients for sleeping ccommodation. The committee states that it has now eceived the sanction of the Commissioners in Lunacy to ts proposed plans for the addition of 90 beds.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8063 births and 3847 eaths were registered during the week ending June 29th. The annual rate of mortality, which had declined throughout he 12 preceding weeks from 17·9 to 12·7 per 1000, urther fell to 12·5 in the week under notice. During he 13 weeks of the past quarter the death-rate in these owns averaged 15·1 per 1000, the rate in London uring the same period being 14·6. The lowest annual eath-rates in the 76 towns during the week were 3·9 n Burton-on-Trent, 4·1 in Hornsey, 6·0 in Leyton, and 6·3 n Willesden; the highest rates were 17·4 in Middlesrough, 17·7 in Sunderland, 19·2 in Huddersfield, and 19·4 n Bolton. The 3847 deaths in the 76 towns showed a urther decrease of 68 from the numbers in recent eeks, and included 427 which were referred to the rincipal epidemic diseases, against 430 and 365 in the wo preceding weeks; of these, 158 resulted from measles, 36 from whooping-cough, 51 from diarrhœa, 40 from carlet fever, 30 from diphtheria, and 12 from "fever" (principally enteric), but not any from small-pox. The eaths from these principal epidemic diseases were equal to n annual rate of 1·4 in the 76 towns, the rate from the ame diseases in London being 1·7 per 1000. No death from ny of these epidemic diseases was registered last week in Villesden, Brighton, Plymouth, Southampton, Birkenhead, Halifax, or in 14 other of the 76 towns; the annual deathrates therefrom, however, ranged upwards to 2·9 in Wigan nd in Bolton, 3·3 in Walsall, 3·4 in Tottenham, and ·5 in Warrington. The fatal cases of measles, which had decreased from 214 to 139 in the six preceding weeks, rose again to 158 in the week under notice; the highest death-rates from this disease were 1·7 in Derby, 2·2 in Warrington, 2·7 in Walsall, and 2·9 in Wigan. The deaths from whooping-cough, which had been 130, 124, and 104 in the three preceding weeks, increased last week to 136, the death-rates from this cause ranging upwards to 1·4 in West Ham, 1·5 in Stockport, and 2·1 in Ipswich. The 51 fatal cases of diarrhœa showed a slight decline from the number in the preceding week, and included three cases in Rhondda, equal to a rate of 1·2 per 1000. The deaths from scarlet fever, which had been 37 and 32 in the two preceding weeks, rose again in the week under notice to 40, of which 13 occurred in London, three in Liverpool, and three in West Ham. The fatal cases of diphtheria, which had been 48, 36, and 27 in the three preceding weeks, were 30 last week, the highest proportional mortality from this disease being in Rochdale, where the rate was 1·2 per 1000. Of the 12 deaths from "fever," two occurred in London, two in Birmingham, and one in each of eight other towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2862, 2936, and 2985 at the end of the three preceding weeks, had further risen to 3022 at the end of last week; 422 new cases were admitted during the week, against 368, 399, and 414 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 186, 149, and 156 in the three preceding weeks, were again 156 last week, and were three below the corrected average number in the corresponding period of the five previous years. The causes of 34, or 0 9 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, West Ham, Bradford, Hull, and 53 other of the 76 towns; the proportion of uncertified deaths, however, showed a marked excess in Liverpool, Birmingham, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 17·2 and 17·3 per 1000 in the two preceding weeks, declined again to 15·0 in the week ending June 29th, but exceeded by 2·5 per 1000 the rate in the 76 English towns. The rates in the eight Scotch towns ranged from 10·0 in Paisley and 10·6 in Leith to 17·0 in Dundee and 22·0 in Greenock. The 522 deaths in the eight towns showed a decrease of 78 from the number in the preceding week, and included 76 which were referred to the principal epidemic diseases, against 83 and 84 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·2 per 1000, which exceeded by 0·8 per 1000 the rate from the same diseases in the 76 English towns; they included 34 which were referred to whooping-cough, 21 to "fever," 13 to diarrhœa, four to measles, three to diphtheria, and one to scarlet fever, but not any to small-pox. The fatal cases of whooping-cough, which had been 57, 43, and 37 in the three preceding weeks, further fell to 34 in the week under notice, and included 20 in Glasgow, six in Dundee, three in Edinburgh, and two in Aberdeen. The deaths referred to "fever," which had been 26, 24, and 14 in the three previous weeks, rose again last week to 21, of which 17 occurred in Glasgow, three in Edinburgh, and one in Dundee; all these deaths, except one in Glasgow, were attributed to cerebro-spinal meningitis. The fatal cases of diarrhœa, which had been eight and 23 in the two preceding weeks, declined again to 13 in the week under notice, and included five in Glasgow, three in Aberdeen, two in Edinburgh, and two in Greenock. The deaths from measles, which had been five and eight in the two previous weeks, decreased last week to four, of which two were registered in Glasgow and two in Edinburgh. Two of the three fatal cases of diphtheria occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 105, 91, and 86 in the three preceding weeks, further fell to 72 last week, but were eight in excess of the number in the corresponding period of last year. The causes of 18, or 3·4 per cent., of the deaths registered during the week were not certified or not stated; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 24·3 and 20·8 per 1000 in the two preceding weeks, further declined to 19·5 in the week ending June 29th. During the 13 weeks of the past quarter the death-rate has averaged 25·4 per 1000, the rate during the same period being 14 6 in London and 17·1 in Edinburgh. The 146 deaths of Dublin residents registered during the week under notice showed a decrease of 10 from the number in the preceding week, and included 11 which were referred to the principal epidemic diseases, against 11, 12, and 19 in the three preceding weeks; of these, eight resulted from whooping-cough, two from diarrhœa, and one from measles, but not any from small-pox, scarlet fever, diphtheria, or "fever." These 11 deaths were equal to an annual rate of 1·5 per 1000, the death-rates during the same week from the principal epidemic diseases being 1·7 in London and 1·5 in Edinburgh. The fatal cases of whooping-cough, which had been four, eight, and five in the three preceding weeks, rose again to eight during the week under notice; while the two deaths from diarrhœa corresponded with the number in the preceding week. The 146 deaths from all causes in Dublin last week included 24 of children under one year of age and 30 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were fewer than the

the milk-sheds which he had visited and said that in some cases where a sterilising apparatus was used it was not milk that was being sterilised but filth. Dr. P. C. Smith thought that too much was being said on the question of milk-supply and too little done. What was wanted was an Act of Parliament which would deal with the whole question in England, Scotland, and Ireland.

DEATH OF A CENTENARIAN.—Mr. Henry D. Hewson died at South Draynes Farm, St. Neot, on June 20th. He celebrated the 100th anniversary of his birthday on March 25th last.

MEDICAL MATTERS IN CHINA.—Dr. Lehmann, who has been for many years medical officer to the German and Dutch residents in Peking, has been appointed by the Chinese Government chief medical and sanitary officer of the province of Mukden for two years. Hitherto this appointment has been in the hands of the Japanese. A German preparatory medical school has just been opened in Shanghai at which 20 Chinese students have already entered. The professors are Dr. C. Dubois Reymond and Dr. Schindler.

THE BARKER ANATOMICAL PRIZE.—This prize is open to any student whose name is on the anatomical class-list of any school in the United Kingdom. The prize is offered this year for dissections to illustrate the muscular and ligamentous anatomy of the shoulder-joint. The prize is of £21 and is awarded by the curator and President of the Royal College of Surgeons in Ireland and the professor of anatomy in the University of Dublin. The preparations entered must be placed in charge of the curator on or before April 30th, 1908. Each must be marked with a fictitious signature and accompanied by an envelope bearing outside the same signature and containing the name of the competitor. Further information can be obtained on application to the curator.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At a meeting of the Honiton board of guardians held on June 1st Mr. Thomas Henry Stocker Pullin, M.D. St. And., F.R.C.S. Edin., M.R.C.S. Eng., L.S.A., was presented by the chairman (Mr. H. Force), on behalf of the guardians, with a silver salver and illuminated address in recognition of his services, extending over a period of 50 years, as medical officer of the Sidmouth, Sidbury, and Salcombe Regis districts of the Honiton union. The chairman alluded to the kindness of Dr. Pullin to the paupers committed to his care, and Dr. Pullin, in returning thanks, said that he had been informed that the length of his service was a record in the Poor-law medical serviec.—On June 22nd Mr. Murray Babington Steuart, M.B., C.M. Edin., was presented with a silver coffee pot, suitably inscribed, and a cheque for 100 guineas, as a mark of respect and esteem from the residents of Bovey Tracey, Devonshire, on the occasion of his departure from the town.

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS: THE COLONY CHALFONT ST. PETER.—The fourteenth annual meeting of the governors of this society was held on July 1st at the London offices, Denison House, Westminster. The chair was taken by Mr. E. Montefiore Michells, and the reports of the honorary medical staff and the executive committee for the year 1906 were received and adopted. From the medical report it appears that during the past year there have been on the average 197 epileptic "colonists" in residence at the society's colony, besides nine convalescent patients. There was only one death during the year. There was entire freedom throughout the year from any epidemic or infectious disease, and the honorary medical staff again testify to the continued usefulness of the colony and generally to the benefits which accrue to the health of confirmed epileptics by the care and management bestowed upon them in the institution, and they add, "It is now universally admitted that a real necessity exists for special institutions in the treatment of epilepsy, and preferably in the form generally adopted in this and other countries—viz., colonies for epileptics." The report of the executive committee states that in response to the appeal recently issued under the auspices of the Prince of Wales as president of the society, besides other contributions, two most generous offers have been received from intending benefactors, one of whom volunteers to provide the entire cost of building an additional home at the Chalfont colony for 24 women, while the other undertakes to provide the cost, estimated at £3500, of building and furnishing a home for the same number of children. To complete the purposes of the appeal, however, funds are still needed for the erection and equipment of two more homes and for other purposes, and an urgent appeal is made by the committee for further funds in aid of this exceedingly philanthropic and much-needed society. The offices are at Denison House, Vauxhall Bridge-road, Westminster, London, S.W.

DONATIONS AND BEQUESTS.—By the will of Dr. Thomas Jarvis Bennett of Tunbridge Wells, subject to his widow's life interest, the whole of his property, valued at over £30,000, is left to the Royal United Hospital, Bath.—Mrs. Godfrey Walker of Conisborough Priory, Yorkshire, the residuary legatee of the late Mrs. Percy Sladen, has sent to the council of the London School of Medicine for Women £20,000 in aid of the endowment of the school.—Mr. John Hughes of Rhyl has by will left about £5000 to be divided between the General Hospital, the Queen's Hospital, the Children's Hospital, and the Eye Hospital at Birmingham.—By the will of Mrs. Henry Moore of Slough, Bucks, King's College Hospital, the Children's Hospital, Paddington, and St. Mary's Hospital will each receive £2000. After certain other disbursements the residue of the estate, valued at £32,000, is left to King's College Hospital.—Mrs. M. E. Bolger has bequeathed by will £1000 each to the Cancer Hospital, Brompton, and the *Chelsea Hospital for Women.* The proceeds of the sale of her furniture, plate, and jewelry are to be given to the Hospital for Consumption, Brompton.

THE HAMPSTEAD GENERAL HOSPITAL.—A special meeting of the medical profession of Hampstead and the neighbourhood was held, under the auspices of the Hampstead division of the British Medical Association, on July 3rd in the lecture room of the Hampstead Conservatoire. The chair was taken by Dr. G. D. Pidcock. The following resolution was put to the meeting and carried *nem. con.*:—

> That this meeting considers that the Hampstead Hospital should always have a visiting staff of local practitioners, and in consideration of this opinion calls upon the members of the medical profession to refuse to accept any office on the staff on terms which are not considered satisfactory by the local profession.

In consequence of the decision of the council of the hospital that in future local practitioners shall not be appointed on the medical staff, a special meeting of governors and subscribers has been requisitioned for July 16th at the hospital at 6 P.M. to consider and, if deemed desirable, to adopt the following motions:—

> 1. That the practice, hitherto followed, of appointing acting medical officers from among the members of the medical profession practising in Hampstead be continued.
> 2. That the number of physicians and surgeons on the consulting staff be augmented.

This requisition is signed by, amongst others, the Mayor of Hampstead, Sir George Barham, Colonel G. Grant Gordon, C.B., and Mr. J. S. Fletcher, M.P., vice-presidents of the hospital; Sir Samuel Wilks, Bart., consulting physician to the hospital; Mr. James Gough, chairman of the house committee; Dr. E. Collingwood Andrews, chairman of the medical committee, on behalf of the staff; Mrs. King and Mrs. Swinburne-Hanham, representatives on the council of the Ladies' Association; Mr. H. W. Birks and Dr. F. P. Weaver, members of council; and Mr. Alderman McMillan, deputy mayor.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Plague in India.

THE memorandum which the Royal College of Physicians of London drew up in July, 1905, on the subject of plague in India, has now been printed as a Parliamentary return. It was moved for by Dr. RUTHERFORD. In this memorandum the Royal College of Physicians drew attention to the grave danger not only to India but to all parts of the Empire which arose from an epidemic of such vast proportions and prolonged duration. Suggestions were made in it for coping with the plague. The memorandum was signed by Sir R. DOUGLAS POWELL, the President, Dr. J. F. PAYNE, Dr. NORMAN MOORE, Sir PATRICK MANSON, Dr. JOHN ANDERSON, Dr. W. J. R. SIMPSON, and Dr. E. LIVEING, the registrar.

Ventilation of Factories and Workshops.

The second report of the Departmental Committee appointed to nd obstinate constipation there is either no mechanical bstruction at all, or if there is any it is at the pylorus or ven in the small intestine. Was the condition of the ppendix vermiformis always carefully noted?"

For mechanical obstruction at the pylorus or in the small ntestine other operations, as is well known, are successfully accomplished. The operation which Mr. Lane dvocates and performs is for constipation caused by a definite, and I fear, seldom recognised, condition of the intestines. The whole colon is stretched and prolapsed; the centre of the transverse portion generally lies, V-shaped, on the floor of the true pelvis. This becomes loaded with scybala. It is the altered position, combined with weakening of the stretched muscular coat, that presents the "mechanical obstacle," eventuating in almost insuperable constipation. The condition leads to other evils, as dilatation of the stomach, loosening of the kidneys, displacement of the uterus, and the cachexia of auto-infection described by Metchnikoff. Mr. Keetley cannot have read Mr. Lane's monograph, in which the whole pathological condition is described with a lucidity that it seems impossible to misunderstand. I recommend its perusal.

May I give a brief outline of a case that has been under my own observation? A female patient, whose bowels had always been troublesome, suffered from nervous breakdown in 1894, ever since which she was the victim of obstinate constipation, the bowels acting only from medicine at three or four days' interval, great difficulty in evacuation being experienced and a sense remaining of something left behind. She came under my care in November, 1902, suffering from constipation, anæmia, weak heart, and uterine retroflexion. The uterus was replaced and supported by a pessary. For 16 months tonics, aperients, enemata, massage, and dieting were employed without amelioration and in March, 1905, Mr. Lane divided the ileum and anastomosed it with the sigmoid flexure. The appendix was examined and found healthy. Conservative surgery permitted it to remain *in situ*. Since the operation the patient has uninterruptedly improved, she has a good colour, has not much difficulty with her bowels, although the rectum has not recovered its normal tone, and she has been able to resume her work, which had been given up in 1903. Once since I discovered scybala in the cæcum. She was conscious of their presence, but in two days they had disappeared without dire result. This, I have little doubt, occasionally happens. Where is the harm? The answer is supplied by the patient's altered appearance and health.

Does the sequel justify the operation? There can be but one reply. Would an appendicostomy, with its small sinus needing constant catheterisation to keep it open—"and patients are careless"—have produced as good results? That we have yet to learn through a larger experience of cases, for which we may be indebted to Mr. Keetley. He has my blessing and encouragement. Let him persevere and, I hope, lead surgery one more step forward on its happy path. Should he succeed, I know one man who will follow his lead with pleasure and accord him full recognition. He is Arbuthnot Lane. Meanwhile let us not belittle or decry, but treat generously the noble work done up to this present by those who have arduously piled stone upon stone on that edifice of which surgery and civilisation are to-day so justly proud.

But perhaps I have misunderstood. I hope so.

I am, Sirs, yours faithfully,

Reading, June 30th, 1907. J. HOPKINS WALTERS.

GROCCO'S TRIANGLE: PHYSICAL AND ANATOMICAL EXPLANATION.

To the Editors of THE LANCET.

SIRS,—Dr. F. W. Forbes-Ross's contribution from the surgical side is a welcome confirmation of the reliability of this sign as one possessing a strictly "anatomical" basis and a "pleximetric" mechanism. We gather once more from his lucid explanation that the spine and the ribs act as a pleximeter, conveying to the surface the muffled character imparted to the percussion vibrations by a distant contact with fluid. The dull area in question represents (and this applies also to the quadrilateral "lower dorsal dull patch" produced by pericardial effusion) neither the shape nor the locality of the fluid accumulation, which is situated elsewhere, but only, and so far as physical conditions will permit, the shape and the zone of influence of the conductor. This was sufficiently dwelt upon in THE LANCET[1] and in the *Polyclinic* (February, 1906), and it was shown that a proof of the correctness of this explanation is contained in the *clinical crucial test* which has enabled me to rely upon this simple and rapid method for a differential diagnosis of free fluid in the pleura and for a recognition of amounts of it too small to be identified by any other means.

Dr. Forbes-Ross's answer to the question "Why is the dull area a triangle?" calls attention to a genuine factor of dulness apparently not previously noted, as no mention of it occurs in the recent review of the subject by W. G. Thayer and Marshal Fabyan in the *American Journal of Medical Sciences* (January, 1907). It is an obvious and important fact that the width of the vertebral column increases from above downwards, and that therefore the costo-spinal groove with its "dull" muscular contents has its maximum width at the level of the twelfth rib and tapers upwards. There are reasons for not regarding this structural peculiarity as a complete explanation of the "triangle," the angles of which, be it stated incidentally, are absolutely sharp in all my own tracings; but as their statement would involve diagrams and occupy too much space I must reserve further comments on that more theoretical question and conclude with a brief preliminary mention of some points of practical clinical interest. 1. I find that it is possible to percuss out two paravertebral triangles in the same subject when both pleuræ contain fluid, and I possess a series of tracings of these double triangles. 2. Fully developed ascites uncomplicated with pleural effusion also gives rise to a paravertebral triangle of relatively small height and with a rather broad base coinciding with the level of the twelfth rib. *The paravertebral triangle of ascites* may therefore be regarded as an additional physical sign of peritoneal effusion. It is always *bilateral*, and, moreover, perfectly *symmetrical* on both sides. In double pleural effusion symmetry of the two triangles has been quite the exception in my series of cases. It is interesting to note in connexion with the paravertebral triangle of ascites that, inasmuch as the diaphragm is raised, we are provided with a proof that a downward sagging of the pleural sac is not an essential factor in the production of the triangle.

I am, Sirs, yours faithfully.

Curzon-street, W., July 1st, 1907. WILLIAM EWART.

THE MEDICAL FACULTY OF THE UNIVERSITY OF LONDON AND ST. GEORGE'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—The vote given on Friday, June 28th, by the Medical Faculty of the University of London must, I think, have been given without a full understanding of the negotiations which have taken place between the Senate of the University and St. George's Hospital. In order that there should be no misapprehension of the attitude of this hospital on the subject I would ask you to extend the courtesy of your columns to the inclosed letter, which I addressed on April 22nd last to the Vice-Chancellor of the University at the request of my board.

I feel confident, however, that the Senate of the University is not to be coerced into breaking the definite undertaking which has been given to this hospital, at the bidding of a majority of five, in a meeting of 149 members of the medical faculty, more especially as I learn that a site, valued at £120,000, and £70,000 in cash have been given for the express purpose of erecting the institute which formed the basis of our negotiations.—I am, Sirs, yours faithfully,

A. WILLIAM WEST,
Treasurer of St. George's Hospital.

St. George's Hospital, S.W., July 1st, 1907.

[COPY.]

St. George's Hospital, S.W., 22nd April, 1907.

To the Vice-Chancellor of the University of London.

SIR,—The board of governors of St. George's Hospital have had it brought to their knowledge that some change of policy is likely to be urged upon the Senate of the University of London, with regard to the concentration of the courses of instruction in the preliminary and intermediate subjects of the medical curriculum. The board respectfully beg you to remind the Senate of the University of the following facts. In July, 1905, an arrangement was concluded between the University authorities and the board of this hospital which provided for: (1) the cessation of any courses of instruction in the preliminary and intermediate subjects of the medical curriculum at St. George's Hospital Medical School; (2) the transference of students and of corps. I regret to learn that some little delay occurred in getting the postman home. Instructions have been issued on the subject.

---

FRIDAY, JUNE 28TH.

Australian Health Legislation.

Mr. VINCENT KENNEDY asked the Under Secretary of State for the Colonies to say what method was used to prevent the landing of persons affected with pulmonary consumption in the Commonwealth of Australia; and whether he would supply fully the details of any legislation existing on this subject.—Mr. CHURCHILL replied: Under the Commonwealth Immigration Restriction Act, 1901, any person suffering from an infectious or contagious disease of a dangerous character is a prohibited immigrant and may be detained for the purpose of medical examination by any officer entrusted with the administration of the Act for a period not exceeding 24 hours in such place and in such custody as he thinks fit. The Secretary of State has no information as to the exact method in which the examination is conducted but will ask the Governor-General of the Commonwealth for a report if the honourable Member desires.

MONDAY, JULY 1ST.

Public Health in Lewis.

Mr. WEIR asked the Secretary for Scotland whether he was aware that, although the local authority in the Island of Lewis had for some years imposed the maximum assessment of 1*s.* per pound for public health purposes, it was quite unable, owing to lack of funds, to give effect to the recommendation of the report by Dr. F. Dittmar, medical inspector for the Local Government Board for Scotland; and would he state why the Board had taken no steps to see that the Public Health (Scotland) Acts were not ignored in this part of the United Kingdom.—Mr. SINCLAIR replied: I am aware, and I am convinced, that in these circumstances it is impossible at present to exercise further pressure upon the local authority.

The Report of a Medical Officer of Health.

Mr. MORTON asked the President of the Local Government Board whether, in view of the recommendations made by the medical officer of health for St. Asaph (Flint), he would ascertain from the local authorities whether they would consider the expediency of dealing with the sewage of the villages of Meliden and Dyserth.

Mr. WEIR also asked the President of the Local Government Board whether he was aware that the medical officer of health for the St. Asaph (Flint) district had expressed the opinion that the sanitation both of St. Asaph and Rhuddlan was unsatisfactory; and would he communicate with the local authority with a view to ascertain to what extent effect could be given to the recommendations of their medical officer of health.—Mr. JOHN BURNS (answering both questions) said: I have just received the report for last year of the medical officer of health and I find that he refers in it to the matters mentioned in the questions. I understand that the rural district committee regards the report as inaccurate and incomplete and has asked the medical officer further to consider it and submit it at the next meeting when the various matters dealt with will be fully considered.

The Bacteriologist to the Local Government Board.

Mr. MORTON asked the President of the Local Government Board, having regard to the fact that the bacteriologist employed by the Local Government Board at the National Vaccine Establishment received a salary of £600 per annum, would he explain why he was allowed to make a profit on vaccine lymph sold to the Local Government Board for Scotland.—Mr. JOHN BURNS replied: The bacteriologist referred to has not hitherto been required to devote his whole time to the duties of his office and he has received an extra payment in respect of his services in connexion with the supply of lymph by the English to the Scottish Local Government Board, such payment consisting of the sum received from the Scottish Board, less the cost of producing the lymph supplied to them. The arrangement has, however, now been altered. The bacteriologist is required to devote his whole time to his duties. He receives an inclusive salary and no extra allowance is payable to him in connexion with the lymph supplied to Scotland.

TUESDAY, JULY 2ND.

Tuberculosis in Ireland.

Mr. VINCENT KENNEDY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state how many persons had landed in Ireland from the United States and other countries within the last year to remain in the country and who were suffering from pulmonary consumption; would he say whether this serious disease was still on the increase in Ireland; and would he acquaint himself with the legislation at present in force in Australia and other British colonies which dealt with preventing the spread of this scourge, with a view to introducing similar legislation at once in Ireland and thus dealing effectively with this drain on Ireland's dwindling population.—Mr. BIRRELL furnished the following written answer: The Irish Government has no information as to the number of immigrants into Ireland who are affected with pulmonary consumption. The proportion of deaths from this disease in Ireland has been practically constant for a good many years past, and in this respect Ireland shows a regrettable difference from the rest of the United Kingdom, in which the death-rate from consumption has been steadily diminishing. The question of undertaking legislation for Ireland in regard to this important matter has already engaged the attention of the Government. I regret that I cannot hold out any hope of immediate legislation, but the matter will not be lost sight of.

Veterinary Surgeons and Public Health.

Mr. SLOAN asked the Secretary for Scotland what were the duties of veterinary surgeons under the Public Health Acts in diseases transmissible from animals to man by milk or meat; what use did the medical officer of health make of the advice given in matters purely veterinary; and whether the veterinary adviser reported through the medical officer of health or direct to the sanitary authority.—Mr. SINCLAIR replied: The duties of veterinary surgeons are contained in Sections 43 and 60 of the Public Health Act, 1897. The use that a medical officer of health will make of any information or advice obtained from the veterinary surgeon will depend on the nature and circumstances of the individual case. With regard to the last part of the question, when proceedings are taken under Section 60, the veterinary surgeon's report, if any, is, in terms of the statute, submitted to the local authority by the medical officer of health. In proceedings under Section 43 there is no statutory rule as to the reports and it is for each local authority to determine whether any report under that section shall be submitted direct or through the medical officer of health. But in all cases it is the duty of the medical officer of health to advise his local authority as to the measures necessary to prevent the direct or indirect transmission of the disease to human beings and, so far as authorised by statute or otherwise, to execute or superintend the execution of those measures.

KING EDWARD'S HOSPITAL FUND FOR LONDON BILL.

On the order for the consideration of this Bill as amended,

Dr. RUTHERFORD moved the recommittal of the Bill with an instruction to the Committee to insert clauses to provide that the control and management should be vested in the President and council, and that the council should be constituted on representative lines. He said that the proposed constitution of the Bill gave the President full and complete power unlimited, uncontrolled, and unchecked. All that he asked was that the council in so far as it was a representative council should be included in the Bill. The public requirements would be met if elected members had seats on it—one from the City of London, one from the London County Council, one from the University of London, one from the Royal College of Physicians of London, one from the Royal College of Surgeons of England, two from the British Medical Association, together with one representative each from the Hospital Sunday Fund, the Hospital Saturday Fund, and the Central Hospital Council. That the whole power should lie in the hands of the President was not fair to him or to the public. It placed him in a position of great responsibility, and no one could enjoy great responsibility without at the same time being open to severe criticism.

Mr. TREVELYAN pointed out that in creating a permanent constitution the House was dealing with an unknown future and personalities of whom they could have no knowledge. He saw no reason why there should not be some representation of public bodies, and he supported the suggestion that the Bill should be recommitted in order that it might be strengthened by a representative element.

Mr. JOWETT supported the amendment. He objected to the suggestion that there should be an overpowering representation of the medical profession controlling the hospitals. Between the years 1897 and 1903 £40,000 subscribed by the public for the conduct of hospitals in reality went to support medical schools. If public support was needed for medical schools let the support be directly applied for. Under the present system all kinds of subsidiary interests connected with the medical profession were sought to be served. The Fund was largely controlled by the medical profession without any real representation of the people. It had also been suggested that the medical profession utilised these hospitals unfairly for their training of future members of the profession and that surgical operations were conducted by men who would not be allowed to carry out such operations upon richer patients outside. All this pointed to the necessity for representative control over the Fund.

The ATTORNEY-GENERAL for ENGLAND (Sir JOHN LAWSON WALTON) said that it was the wish of the highest persons interested in the proposals of the Bill that the matter should be left to the consideration of Parliament, and any provision Parliament would think wise would be cordially accepted by those intrusted with the administration of the Fund. No one had cavilled at the powers of the present President during the time he had been graciously disposed to discharge the duties of the office, but it was contemplated that on the resignation of the Prince of Wales of the position of President there might be a question in reference to his successor and the qualifications his successor might possess for the discharge of duties and responsibilities which legislation might thrust upon him. The suggestion was put before the House of Lords Committee and a provision was introduced that on the termination of the tenure of office by the present President the office should pass to his successor to be chosen by the unanimous recommendation of the very prominent individuals who were named in the Bill. When the Prince of Wales resigned his place as President it would be necessary for the Lord Chancellor, the Prime Minister, and the Governor of the Bank of England for the time being to concur in the recommendation of some member of the Royal Family whom they considered qualified to accept the post now occupied by the Prince of Wales. Therefore there was assurance that three persons holding high and responsible public positions would unite in recommending a qualified person. But if they did not concur then the duties of President would devolve into the hands of three persons. There would be no longer a President but three Governors. It was said that the council ought to be elected, but the difficulty was to give the council an elective character, seeing that it was impossible to specify a constituency to carry out the election. It had further been suggested that this constituency should largely consist of the members of the medical profession; and, again, it had been suggested that subscribers to the Fund should be the electorate, and if that was adopted he believed that the majority and those who contributed the largest amounts had no wish to interfere with the discretion of the Royal Family. It was clear, however, that there would be a large representative element in the council.

Dr. RUTHERFORD: What we ask is that this should be inserted in the Bill.

The ATTORNEY-GENERAL replied that he was trying to satisfy honourable Members that that was not necessary. If public confidence was to be secured it was obvious that the constitution of the council must be maintained and possibly a larger representative element would be required in the future, but he suggested it was undesirable to stereotype this representation. In any scheme for hospital management there must be a large representation of the medical element. There had been proposed a clause limiting the individual power of the President, so that on his own part and on his own authority he could deal with neither the distribution, nor the investment, nor the application of the property, and that covered nearly the whole of the objects of the Fund. The President was thus controlled by the majority of his council in all matters relating to the investment, expenditure, application, and

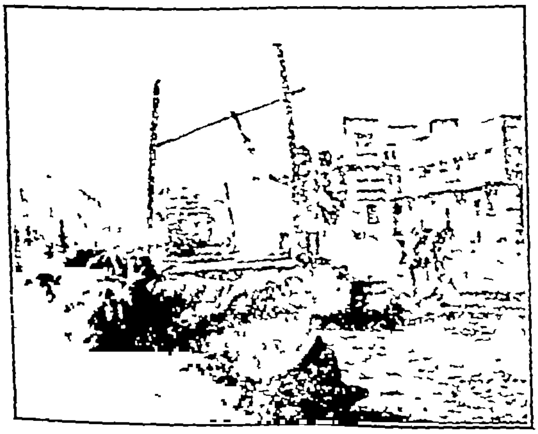
THE WATER SUPPLY OF JEDDAH (*continued*).

Well Waters; Wells in the Town and in the Desert.—Tube Wells.—Mode of Distribution of the Water.—General Inadequacy of the Supply both in Quantity and Quality; Threatened Water Famine.—Decision to put up Condensers.

Well waters.—There are a considerable number of wells in Jeddah, in the courtyards of the houses or "hoches." They are mostly "shallow" wells, and are often situated dangerously close to cesspools in the same yard. There are a few public wells in the streets; they are rarely properly protected from surface impurities. Near the Mecca Gate, however, there is a row of five large, deep wells with good parapets round and the masonry lining in fairly good condition. They may be seen in Fig. 31. Well water in Jeddah is always brackish; it is said to be employed solely for washing or other external purposes. Anyone can come and take the water, but it appears to be distributed mostly by the "saggas," or men who carry the water in skins or petroleum tins and sell it at about a penny the large skin, or a halfpenny the petroleum tin.

FIG. 31.



Wells near the Mecca Gate.

Outside the walls of Jeddah an infinite number of wells have been dug in the desert. If one goes along the Mecca road for a few hundred yards it can be seen that on either side of the road the desert is literally honeycombed with old wells. The curious aspect this produces is seen in Fig. 32. The depth of these wells varies greatly; some were only ten or 12, others 30 or 40, feet deep. When such a well is dug in the desert the water produced is at first drinkable though rather brackish; at the end of ten or 15 days it becomes still salter and a little later it is absolutely undrinkable. The well is then abandoned and a new one dug. In this way the sinking of wells is a process that never ceases. There are said to be four districts where the wells are most abundant; they are called Kharij el-Hanesh, Sururis, Gholel (all three to the south of the town), and Nisyan (to the north). The water obtained from these wells seems to putrefy with exceptional rapidity; it is said to be impossible to keep it in a house longer than 24 hours. Some of the wells near Jeddah that I looked into contained only a small quantity of stagnant water at the bottom covered with a green scum.

In 1900 two specialists, one of whom was said to have done successful work at Hodeidah, arrived at Jeddah with the object of making some experimental borings for tube-wells. The first borings were made near the sea, close to the building occupied by the municipality. At a depth of 80 feet they met with salt water. A second attempt, in the northern part of the town, led to no result, as a rocky stratum was met with which their instruments were unable to pierce. Then four wells were bored near the Municipal Hospital. At first each of these borings yielded three tons of water daily; the water is said to have been a little brackish but drinkable. But the yield gradually diminished and the quality of the water deteriorated. The tubes became more or less blocked with sand, the pumps were too weak, and all were abandoned save one. The tube of this well has a diameter of about one and a half inches. The pump, over which a small shed has been built, is at the free disposal of the public. The depth of the well is only some 12 metres (40 feet), as instruments for a deeper boring were not at hand. The water yielded is slightly brackish. Another well of the same kind was bored in the garden of the Kaimakam (Governor) of Jeddah and still remains; it is only used for watering the garden.

FIG. 32.

Wells in the desert near Jeddah: the road to Mecca on the right between sandhills.

It will be seen from the foregoing that both as regards source and quantity the water-supply of Jeddah is in a very unsatisfactory state. The method of distribution of the water is not less unsatisfactory. The water is distributed either in goat- or sheep-skins or in empty petroleum tins; these are carried by camels or donkeys, or (less often) by men called "saggas." The skins retain the complete form of the animal during life, except for the absence of the head; they

Notes, Short Comments, and Answers to Correspondents.

CHARGE AGAINST A MEDICAL MAN FOR OBSTRUCTING THE HIGHWAY WITH HIS MOTOR-CAR.

A VERY curious charge was recently brought against Dr. R. H. Spencer, a practitioner of Alcester, by the Inkberrow police for obstructing the Worcester-road in that place. The car had stood outside a house in which Dr. Spencer was paying a professional visit and a police-constable stated that whilst it was standing there he had seen two horses shy at it and refuse to pass it. On cross-examination by Dr. Spencer's solicitor he admitted that the road was 19½ feet wide and that the car was only 4 feet 9 inches across at its widest part. The car was silent. The witness had made no attempt to draw its owner's attention to the matter until he came out of the house. He considered that the road was obstructed by the car and that the people of Inkberrow were entitled to the whole of the road just as much as Dr. Spencer, which, seeing that his car was not occupying a quarter of it, appears a singular argument. The defence was that there had been no wilful obstruction and that there was no case to answer, and the bench concurred in this view and dismissed the case. The police superintendent intimated that he should ask the bench to state a case. We congratulate Dr. Spencer on the result, but it is annoying to be put to the trouble and expense of answering such an unlooked-for charge. We record the case as one of some importance to medical men, for had it succeeded it would have afforded a precedent that would have brought all medical men who perform their rounds in motor-cars within daily peril of the law. We do not, of course, know whether the matter may be taken to a higher court.

SPEED VERSUS COMFORT ON RAILWAYS.

To the Editors of THE LANCET.

SIRS,—It is difficult to see the precise object of Mr. Edge's recent wonderful feat of endurance, and I would undertake to make a motor-car travel a greater distance in 24 hours by mounting it so that it could travel on a circular railway track and eliminating the driver altogether. But seriously, is not this craze for excessive speed rather overdone? What the ordinary traveller wants is not to be banged along at 60 miles an hour but to go at a good moderate speed *under comfortable conditions.* This is a requirement not much studied by our railway companies, who even for quite long journeys provide nothing better than suburban carriages in defiance of all reasonable requirements of our physical economy. Every long-distance train ought by law to consist of corridor coaches only, fitted with lavatory accommodation; and the provision of a buffet where light refreshments could be obtained would be a welcome, though not so necessary, addition. I wish that some distinguished medical man could be induced to take this question up in the interests of the travelling public, who are quite at the mercy of the railway companies in this matter.

I am, Sirs, yours faithfully,

July 1st, 1907. AN OCCASIONAL TRAVELLER.

1 cargoes at the docks, and this damaged grain heats forms a fine soil for the growth of moulds and bacteria. revent its use for human food the medical officer and ector see it to its destination, and it appears that this n grain, "which contains considerable colonies" of gerous bacilli, is used for making some kind of poultry . It is not a pleasant idea that the chickens which buys may have been fed on revolting and unwholesome se and that eggs are eaten which come from fowls fed on same undesirable kind of stuff.

St. Mary's Hospitals.

he annual meeting of the friends and supporters of the Mary's Hospitals was held on June 19th. The work ch had been done during the last year was extremely vy but, as usual, while the work presses forwards the ns for carrying it on lag behind. The expenditure last r was £10,908, while the total income was only £6956, ing a net deficit on the year's working of £3952. At the l of 1905 the deficit balance was £8763. There is a further icit balance of £12,400 remaining on the building account the hospital in Whitworth-street West which has been nsferred to the general account, so that the total adverse ance at the end of 1906 amounted to £25,000. Towards eting this, £12,000 out of capital funds have been drawn which, of course, means a smaller income from investnts. Expenses are being curtailed; the Clifford-street spital—i.e., the old Southern Hospital—is to be closed d the gynæcological and children's beds transferred Whitworth-street West till the new hospital in Oxfordeet and High-street is ready for their reception. An rnest appeal was made for generous help, the chairman minding the public that if the work of St. Mary's Hospitals s not done there was no other existing institution to take up. These hospitals have always done an unostentatious t most valuable work for the poor mothers and children of anchester, and if more of the well-to-do people of Manester thought about it and tried to realise it there would no difficulty in getting the help required.

Medical Man and the Midnight Visitor.

Dr. G. E. Orme of Clitheroe had an exciting adventure on e night of June 27th. He went to his bedroom about ddnight, when a man without his shoes dashed past him wards the stairs. Dr. Orme followed, threw his suspicious sitor, and held him till a policeman, telephoned for by rs. Orme, arrived and took the man into custody.

July 3rd.

VALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Treatment of Tuberculosis at Merthyr Tydvil.

The Poor-law inspectors of the Local Government Board have upon several occasions reported upon the excellent administration of the infirmary which is attached to the workhouse at Merthyr Tydvil. The medical officer to this institution, Mr. J. L. W. Ward, opened a discussion upon the best methods of treating tuberculous patients by Poor-law authorities at a conference of members of boards of guardians held at Merthyr on June 26th. While recognising the necessity for improving the houses and the surroundings of the working classes Mr. Ward considered that the evidence in favour of sanatorium treatment of the disease was undeniable. He advocated the establishment of inexpensive buildings in connexion with workhouse infirmaries where selected cases could be properly treated. In the Merthyr Infirmary, where there does not appear to be any special provision made for these patients, there were treated during the past three years 128 cases of pulmonary tuberculosis, of which number 47, or 36 per cent., terminated fatally.

Sanitation of Aberdare.

Notwithstanding the high death-rates which have been recorded in Aberdare in recent years, together with the prevalence of infectious disease and an unusually high rate of infantile mortality, the urban district council has shown little or no desire to improve the sanitary condition of the town which has a population approaching 50,000. The recently issued report of Dr. J. Spencer Low, a medical inspector of the Local Government Board, appears to have stimulated the council to activity in some directions. At a special meeting of the authority held to consider the recommendations contained in the report it was decided to take steps to provide a proper isolation hospital. This decision was apparently come to with reluctance, for one member of the council remarked that he "did not like to waste the ratepayers' money, but in this case it could not be avoided." Other recommendations of Dr. Low were either referred to the health committee or their consideration was deferred.

Vaccination Fees at Warminster.

At the meeting of the Warminster (Wiltshire) board of guardians, held on June 24th, it was resolved not to reduce the fees of the public vaccinators in October next. This course was adopted owing to the fact that the public vaccinators of the Warminster union were the only ones in Wiltshire who, in 1898, accepted the minimum fees allowed under the Act.

The Pharmaceutical Society and the Sale of Poisons.

At the Plymouth county court on June 26th a druggist's assistant was summoned for having sold poison contrary to Section 15 of the Pharmaceutical Act of 1868. Evidence showed that the defendant had sold cough medicine containing morphine and he was fined £5 and costs. The prosecution was instituted by the Pharmaceutical Society.

Paignton Waterworks.

The works at Holne Moor, Dartmoor, constructed at a cost of £111,000 for the Paignton urban district council to supplement the water-supply of Paignton, and also to afford supplies to Teignmouth and Brixham, were formally opened on June 26th by Mr. Layland Barratt, M.P., in the presence of a large gathering.

July 1st.

SCOTLAND.

(From our own Correspondents.)

The Work and Objects of a Nurses' Training Home.

Considerable dissatisfaction is being expressed by the medical practitioners in Govan in connexion with the methods adopted at the Nurses' Training Home and the questions involved are of wide general interest. The home provides nursing in their own cottages for the working classes and poor in the district of Govan and elsewhere and trains women as cottage nurses and certificated midwives for work in rural and other districts. In the home lectures are given to the nurses by medical men and instruction in nursing is given by the matron. The practical experience is gained by the pupil nurses going out to nurse patients in their own homes, either with or without the supervision of a medical man. In some cases the nurse resides in the patient's house but in most cases the nursing is done by visits to the patient once or twice daily. The midwifery training is by lectures in the home from a medical man and by practice on patients in the neighbourhood under the supervision of the midwife of the home. This period of training extends in all to six months and is supposed to be sufficient to enable the students to be sent to country districts as cottage nurses and rural midwives. It is contended for the system that a body of nurses is being trained who can undertake in the houses of the working class and poor duties such as cooking, washing, and the care of children in addition to the nursing of the patient. The minimum fee for the midwife is 7*s.* 6*d.*, and this is supposed to be restricted to houses where the householder's average weekly wage does not exceed 30*s.* The contention of the medical men of the district is that the home enters into unfair competition with the medical men, seeing that cases other than maternity ones are being treated by the nurses without a medical man in attendance, whilst in deciding what houses are eligible to be attended by the nurses no account is taken of the income of the family. It is also suggested that the real aim of the home is not so much the benefit of the poorer inhabitants of Govan as the turning out into country districts of women imperfectly trained as nurses and midwives. The executive committee of the home was approached by the Govan Medical Association in connexion with the matter, but although some concessions were made as regards the rules regulating the relations of the nurses to their patients, the medical practitioners of the district think that they still have grounds for dissatisfaction.

Notes, Short Comments, and Answers to Correspondents.

CHARGE AGAINST A MEDICAL MAN FOR OBSTRUCTING THE HIGHWAY WITH HIS MOTOR-CAR.

A VERY curious charge was recently brought against Dr. R. H. Spencer, a practitioner of Alcester, by the Inkberrow police for obstructing the Worcester-road in that place. The car had stood outside a house in which Dr. Spencer was paying a professional visit and a police-constable stated that whilst it was standing there he had seen two horses shy at it and refuse to pass it On cross-examination by Dr. Spencer's solicitor he admitted that the road was 19½ feet wide and that the car was only 4 feet 9 inches across at its widest part. The car was silent. The witness had made no attempt to draw its owner's attention to the matter until he came out of the house. He considered that the road was obstructed by the car and that the people of Inkberrow were entitled to the whole of the road just as much as Dr. Spencer, which, seeing that his car was not occupying a quarter of it, appears a singular argument. The defence was that there had been no wilful obstruction and that there was no case to answer, and the bench concurred in this view and dismissed the case. The police superintendent intimated that he should ask the bench to state a case. We congratulate Dr. Spencer on the result, but it is annoying to be put to the trouble and expense of answering such an unlooked-for charge. We record the case as one of some importance to medical men, for had it succeeded it would have afforded a precedent that would have brought all medical men who perform their rounds in motor-cars within daily peril of the law. We do not, of course, know whether the matter may be taken to a higher court.

SPEED VERSUS COMFORT ON RAILWAYS.

To the Editors of THE LANCET.

SIRS,—It is difficult to see the precise object of Mr. Edge's recent wonderful feat of endurance, and I would undertake to make a motor-car travel a greater distance in 24 hours by mounting it so that it could travel on a circular railway track and eliminating the driver altogether. But seriously, is not this craze for excessive speed rather overdone? What the ordinary traveller wants is not to be banged along at 60 miles an hour but to go at a good moderate speed *under comfortable conditions.* This is a requirement not much studied by our railway companies, who even for quite long journeys provide nothing better than suburban carriages in defiance of all reasonable requirements of our physical economy. Every long-distance train ought by law to consist of corridor coaches only, fitted with lavatory accommodation; and the provision of a buffet where light refreshments could be obtained would be a welcome, though not so necessary, addition. I wish that some distinguished medical man could be induced to take this question up in the interests of the travelling public, who are quite at the mercy of the railway companies in this matter.

TUESDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Clinical Lecture:—Mr. Dunn.

that for the week ended June 22nd 16 cases of cerebro-spinal meningitis had been notified, as compared with 17 in the previous week. Since the last meeting of the committee (June 20th) 14 cases of cerebro-spinal meningitis were notified, as against 17 during the previous week, and during the week ended June 22nd 20 deaths were registered as being caused by the disease. Of 84 patients in Purdysburn Fever Hospital 39 were suffering from the disease, 15 from scarlet fever, and 19 from typhoid fever.—Cerebro-spinal fever has broken out among the militiamen in Ballykinlear camp, near Newcastle, two cases having been removed to Purdysburn. Typhoid fever has also broken out amongst the troops in the barracks at Holywood, near Belfast.—At a meeting of the city corporation of Belfast, held on July 1st, the report of the medical superintendent officer of health for the period from May 19th to June 15th was read and from it it appears that the number of cases of infectious diseases notified during the four weeks was 192, as compared with 305 in the preceding five weeks, the most marked decrease being in the number of cases of cerebro-spinal meningitis, which numbers 74, as compared with 139. There is a slight increase in the number of cases of erysipelas, whilst the number of cases of typhoid fever and membranous croup is about the same. The average annual death-rate from all causes was 21·9. Attention was drawn to the fact—by the chairman of the baths and lodging house committee—that while a few weeks ago they proposed to admit school children to the baths free of charge on one day of the week, up to the present the Commissioners of National Education had not agreed to the proposal.

Down District Asylum.

From the report of this asylum for 1906 it appears that during the year 468 men and 389 women were under treatment. Mr. M. J. Nolan, the resident medical superintendent, does not think there has been any actual increase in insanity in the district. His views on the causes of insanity in Ireland are interesting and I give them in full:—

> In a country on which the scourge of insanity has fallen with such an unusually heavy hand the local circumstances of this county are such as to enable it to resist, with some degree of success, the inroads of this terrible evil; and so we may, perhaps, learn the lesson that the prevention of insanity is to be achieved, if achieved at all, by an all-round improvement in the social life of the people. Freedom from the worst miseries associated with dire poverty, from the wearing strain of agrarian agitation, and, above all, from the mental unrest associated with rapidly declining prosperity (evident in the less fortunate districts), all combined with a marriage- and birth-rate higher than the average, a decline in the emigration rate, and a generally fairly prosperous condition of things, due in a great degree to the characteristics of the people themselves, the county of Down stands in the satisfactory position of having but one registered lunatic in 216 of its population, at a time when the average in the country is one in 178.

The average cost of each patient for the year was £22 15*s.* 4*d.*, while the net average cost, deducting repayment of loans, receipts from paying patients, and other miscellaneous receipts from the gross expenditure, was £20 9*s.* 1*d*, as against £22 2*s.* 4*d.* in the previous financial year—a reduction of £1 13*s.* 3*d.* per head. In every respect this report of Mr. Nolan is a most interesting and satisfactory one.

July 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Fractures of the Clavicle.

THE papers read at the meeting of the Surgical Society on June 12th included one by Dr. Couteaud of the Naval Medical Service on the treatment of fractures of the clavicle. For several years he has treated these fractures by rest in bed, the shoulder of the side affected being at the same time placed in a certain position. This method was not only in accordance with physiological principles but was efficacious and capable of being put in practice by anyone. Complaints have been made that it was uncomfortable but this was a trivial objection to a surgical procedure which aimed at the avoidance of deformity (*chirurgie esthétique*). Allowing the arm to hang vertically over the edge of the bed caused relaxation of the contraction and stiffness of the muscles of the shoulder, a condition which was advantageous for coaptation. Swelling of the upper limb was therefore to be desired rather than feared, but it seemed to be unnecessary to maintain this attitude for more than two or three days, and it was better at the end of this period to bend the elbow and allow the forearm to rest on a pillow; this position was certain to bring about the automatic juxtaposition of the fractured ends. The œdema which this method of treatment caused was of no serious importance, being of brief duration and easily relieved. Dr. Couteaud recommended that rings which the patient might be wearing should be removed. The duration of the treatment varied from 15 to 21 days.

Blackening of the Tongue caused by Peroxide of Hydrogen.

At a meeting of the Paris Society of Medicine held on June 8th M. Bizard read a paper on blackening of the tongue. The remarkable condition, to which Walerand has given the name of *langue noire pileuse* (hairy black tongue), seemed to be produced by very different causes, about most of which there was little definite knowledge. Many of the cases proceeded simply from foreign substances accidentally colouring the extremities of hypertrophied papillæ. Of this kind was the instance observed by Chatin, in which there was a decided black tint of the dorsal aspect of the tongue in several syphilitic patients who were taking mercury and making use of a gargle containing diluted peroxide of hydrogen. In the course of a week M. Bizard saw blackening of the tongue in two syphilitic patients under his care who were treated with injections of grey oil and mouthwashes of a solution of peroxide of hydrogen. It might have been supposed that the peroxide of hydrogen on coming into contact with the saliva of the mercurialised patients gave rise to a reaction which produced a brown colouration of the extremities of the lingual papillæ, but the fact was that peroxide of hydrogen might by itself cause blackening of the tongue. In a man habitually enjoying good health, not syphilitic, and free from constitutional defects, but a smoker and the subject of hypertrophy of the lingual papillæ, the daily use of a gargle of peroxide of hydrogen in half a tumblerful of warm water produced in eight days a very pronounced blackening of the dorsal aspect of the tongue. This disappeared in a few days when the peroxide of hydrogen was stopped and the surface of the tongue soon afterwards desquamated in large flakes.

Suggested Employment of Radioscopy and Radiography in Meat Inspection.

Calcareous deposits are readily formed in the tuberculous lesions of the ox and the pig, and at a meeting of the Academy of Sciences held on June 12th M. Martel suggested that the recognition of such deposits by means of the Roentgen rays might be useful as an indication of deep-seated isolated tuberculous centres, especially in the interior of the superficial or deep glands which were always more or less imbedded in fat. When the meat could be conveniently spread out for examination radioscopy clearly showed the tuberculous portions. Healthy glandular tissue cast little shadow with the rays as it was almost transparent to them, but tuberculous glands cast a shadow of granular appearance varying in intensity according to the amount of calcareous infiltration. Isolated lesions were recognised by their shadows having the granular aspect which indicated the presence of salts of lime. Meat which gave a negative result on examination with the Roentgen rays might, however, be tuberculous. Proper allowance being made for its limitations, the method had the advantages that the meat did not require to be cut and that the examination took very little time.

The Medical Profession in Narbonne.

I do not propose to refer to the political unrest and agitation in the south of France except in so far as it has affected the medical profession. The military authorities having refused to supply the medical men of Narbonne with the passes necessary to enable them to visit patients in the disturbed districts these practitioners have published a letter informing the townspeople that they cannot promise to attend patients regularly in the area occupied by the troops. They have also published the letter in which their request for passes was refused. It has been the practice for three practitioners to be selected by the military authorities each month for the purpose of giving advice with respect to the discharge of soldiers unfit for service (*réforme*), but a meeting has now been held at which it was resolved to discontinue this work. The practitioners also refuse to attend the gendarmes of the district.

Officinal Preparations of Mistletoe.

M. R Gaultier, in presenting to the Therapeutical Society a work sent by M. Delassus, said that he had himself observed a distinct and long-continued reduction of the arterial pressure when pills containing aqueous extract of mistletoe were administered. Some fresh clinical facts induced him to consider this substance as hypotensive

July 1st.

Agent for the Advertisement Department in France—J. ASTIER, 81, Rue Bapts, Asnieres, Paris.

termali," and other products, alimentary and hygienic, relating to physical therapeutics, dietetics, balneology, and climatology, and together with these a collection of plans, designs, photographs, descriptions, coloured and printed, and monographs illustrative of the various health resorts, climatic stations, and balneary "cures," and some notion will be formed of the attractions offered to those of the profession who are interested in this department of medicine. Among the exhibitors at this exposition many leading houses in France, Germany, the British Isles, and America will be represented alongside those of Italy in the *locales* specially provided *ad hoc*, namely, the suite of rooms attached to the Clinica Medica of the Policlinico, with the addition of others should these prove insufficient. For all exhibits intended for this Exposition the Minister of Public Works has conceded a reduction of 50 per cent. on the charge of transport over all the railway lines of Italy, a reduction which will include not only the journey in but the return journey out, should the said exhibits not be disposed of at the Exposition. Finally, a special jury is being organised to appraise the competing exhibits and to award the prizes and marks of distinction among the competitors.

The Alpine "Accident" Season.

I learn from Bellinzona, the capital of Italian Switzerland, that this "season" has made its normal commencement in the "playground of Europe." All the favourite peaks are being "stormed" by adventurous climbers, many of these latter hailing from Italy, where the "furore" for Alpine exploration has reached the point of an "obsession." Two parties have successfully scaled the Matterhorn, one party Mont Blanc, and another the Jungfrau. There are, however, three "casualties" to be registered. A young lady (aged 22 years) has been killed by a fall of 80 metres on the mountains of Andey; a gentleman has lost his life similarly by a fall on the rocks of Chez-Marqueret; and a boy, aged 18 years, from Göschenen, while gathering flowers in the mountain valley of Ossemburg also lost his footing with fatal consequences.

The Civic Honours to Lord Lister.

No foreign name is more honoured among Italians than that of the "Inventore della Medicazione Antisettica," except it be that of Pasteur. Thanks to these two "heroes of science" the surgeon's art in Italy, always conspicuous for its "assured touch" and its "artistic dexterity," is no longer shadowed by the high death-rate that used to compromise it. As I write, all the leading journals of the evening report the conferring of the Freedom of the City of London on Lord Lister in terms of cordial approbation—some of them, the "Corriere della Sera" of Milan, for instance, adding a brief biographical note on the career of the "venerando scienziato."

June 29th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Tropics as the Future Centre of Civilisation.

Colonel W. C. Gorgas, chief sanitary officer of the Isthmian Canal Commission, in an address before the graduating class of the Cornell Medical College, predicts that within the next two or three centuries the tropics will be the centres of wealth, civilisation, and population, as they were in the dawn of human history. This prediction is based on his experience in sanitation in the Panama Zone. He stated that through the efforts of the sanitary branch of the commission malaria and yellow fever have been brought under control. There has been no yellow fever on the Isthmus of Panama for over a year and malarial fevers have been reduced to a minimum. So completely has the stegomyia been reduced in numbers that yellow fever would not spread if it were introduced. He says that among the 6000 Americans connected with the canal work, which number includes 1200 American women and children, the families of these employees, there is very little sickness of any kind and their general appearance is fully as vigorous and robust as that of the same number of people in the United States. He concludes that the sanitarian can now show that any population coming into the tropics can protect itself against these two diseases by measures that are both simple and inexpensive; that these two diseases eliminated, life in the tropics for the Anglo-Saxon will be more healthful than in the temperate zones; and that gradually within the next two or three centuries tropical countries, which offer a much greater return for man's labour than do the temperate zones, will be peopled by the white races and become the centres of wealth, population, and civilisation.

Membership of the American Medical Association.

The recent report of the secretary of the American Medical Association shows that its membership on May 1st, 1907, was 27,515. The changes in the membership during the preceding year show the condition of the association. The discontinuances were 2135, of which 258 were by death, 1005 by resignation, 424 were dropped for non-payment of dues, 419 were found to be ineligible, and 29 were not traced. The comparatively large number of non-eligible members dropped was due to a systematic revision of the membership list. There have been added to the list during the year 6014 names, giving a total membership of 27,515, as already stated.

A Law Authorising the Sterilisation of Defectives.

An Act has passed the Legislature of the State of Indiana entitled "An Act to Prevent Procreation of Confirmed Criminals, Idiots, Imbeciles, and Rapists." The preamble states that "heredity plays a most important part in the transmission of crime, idiocy, and imbecility." The law provides that it shall be compulsory for each and every institution in the State entrusted with the care of confirmed criminals, idiots, rapists, and imbeciles to appoint upon its staff, in addition to the regular institutional physician, two skilled surgeons of recognised ability whose duty it shall be, in conjunction with the chief physician of the institution, to examine the mental and physical condition of such inmates as are recommended by the institutional physician and board of managers. If in the judgment of this committee of experts and the board of managers procreation is inadvisable and there is no probability of improvement of the mental condition of the inmate, it shall be lawful for the surgeons to perform such operation for the prevention of procreation as shall be decided safest and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable.

Pasteurisation of City Milk.

The board of aldermen of New York has decided that the pasteurisation of the milk sold in New York is neither necessary nor desirable, notwithstanding the vast array of facts that were brought forward to prove the contrary. The result of the discussion, however, has been very useful, not only in the city but throughout the country, in creating a public sentiment in favour of measures to secure a pure milk-supply. The first measure which attracts the public is that of securing a pure quality of milk directly from the dairy by the sanitation of the entire dairy establishment. Over the entire country public attention is being directed to the condition of the local dairies supplying the communities and greater and greater pressure is being brought to bear upon the milk producers in regard to the necessity of having their dairies in perfect sanitary condition. Health authorities, while insisting upon the improvement of the dairies, affirm that this will be a very gradual reform, but meantime pasteurisation of the milk for the public must be adopted as the only available method of sterilising the milk. The milk commission of Washington represents the position of the health authorities throughout the country in a recent report. It states as follows: "It must be apparent that it will require time and education to secure compliance with even reasonable safeguards and it is equally evident that the number of dairy farms now in a position to live up to sanitary requirements will supply but a small percentage of the population, although it is hoped they will be stimulated into existence by trade competition and the refusal of the public to buy dirty milk at any price. Until this is accomplished the committee, in the interests of public health, strongly advocates clarification and pasteurisation of all milk."

Industrial Settlement for Tuberculosis.

The Saranac Lake Industrial Settlement has been formed to give employment to persons who have reached the arrested stage in pulmonary tuberculosis and can no longer remain in institutions for incipient cases. This improvement in the treatment of the subjects of tuberculosis has been inaugurated under the direction of Dr. E. L. Trudeau, to whom this country owes so much for his pioneer work in the care of the victims of tuberculosis. It is held that this class of persons should not return to city conditions in order to support themselves, and to this end light employment along the lines of gardening, poultry raising, &c., is to be undertaken.

June 24th.

Russia, Poland, and Finland, most people will allow the mortality is serious. 5,000,000 deaths from plague in Europe would be considered on this side of the Red Sea appalling in whatever way it was distributed. And if it happened that many of the countries in Europe were more or less free from plague and that the disease concentrated itself on three or four countries, such as France, Italy, Austria, and Great Britain and Ireland, causing in these nearly 4,500,000 deaths out of the 5,000,000, the mortality would be viewed as a catastrophe of the first magnitude. But if in addition to the loss of the 4,500,000 of inhabitants there were, owing to the recurrence of the disease, a prospect of several more millions being destroyed in those places already attacked, and that there was the further danger as the pandemic developed of the other countries—such as Germany, Holland, Spain, Greece, and Turkey—being attacked in the same way, then the situation of Europe would be similar to that of India to-day. This will serve to give some conception of the tragedy which is going on in India at the present time and of the future perils of that unhappy country. It is a misconception, fraught with the greatest danger, to suppose that in India the plague is only causing a death-rate of 3 per 1000, as was stated in the House of Commons during the debate on the Indian Budget. The figures giving the total number of deaths in the different provinces of India since September, 1896, exhibit a very different degree of incidence and severity in each. The Madras Presidency has escaped with a comparatively small number of deaths; so have most of the other provinces. Four provinces have hitherto borne the brunt of the epidemic in India out of the 15 presidencies, provinces, and States into which India is divided. These are the Bengal Presidency, with a little over 500,000 deaths; the Bombay Presidency, with a little over 1,500,000 deaths; the United Provinces, with nearly 1,000,000 deaths; and the Punjab, with over 1,750,000 deaths.

The annual returns for these provinces are approximately represented in the following figures:—

Year.	Bombay and Sindh, population 22,000,000.	Bengal, population 74,000,000.	United Provinces, population 47,000,000.	Punjab, population 25,000,000.
September, 1896, to end of 1897	57,000	—	80	179
1898	104,000	166	116	1,800
1899	117,000	3,000	6	250
1900	38,000	37,000	116	500
1901	168,000	78,000	9,000	18,000
1902	217,000	32,000	43,000	222,000
1903	340,500	65,000	80,000	210,000
1904	281,000	75,000	179,000	402,000
1905	96,000	126,000	383,000	389,000
1906	71,000	50,000	57,000	93,000
To May 11th, 1907...	52,000	50,000	223,000	432,000

THE EPIDEMIC IN THE PUNJAB.

The province of the Punjab which has lost nearly 1,750,000 of its inhabitants is in size less than one-twelfth the total area of India and it contains less than one-eleventh part of its population. It is slightly larger in area than Great Britain but is smaller than Great Britain and Ireland. Its population, including the Native States, is 25,000,000 without the Native States 20,000,000, against the 43,000,000 of Great Britain and Ireland, so it is not a large province, and the loss of 1,750,000 out of 25,000,000 can only be viewed as an appalling disaster. If plague had destroyed 3,000,000 of the inhabitants of Great Britain and Ireland in ten years it would have represented proportionately what the Punjab has lost during that time with its smaller population. The plague began very slowly in the Punjab and took six years before causing 250,000 deaths. There were 179 deaths in 1897, 1871 in 1898, 253 in 1899, 525 in 1900, then, as reported by the Sanitary Commissioner for the Province, all restrictions were removed and a new policy was introduced; in 1901 there were 18,877 deaths and in 1902, 222,533 deaths. The great mortality has been during the past four and a half years and the greatest during 1907, when over 500,000 deaths occurred during the first five months, which is the epidemic season. 800,000 deaths from plague occurring in Great Britain and Ireland in five months would represent the intensity of the epidemic in the Punjab during the early months of this y There is no comparison between 800,000 deaths and 54, which was the largest epidemic of cholera in Englan 1854–55 and which was considered to be appalling in country. During the week ending May 11th, when climax of the present year's epidemic in the Punjab reached, there were 60,000 deaths from plague in province, which in the British Isles would be represente 100,000 deaths in one week in an epidemic of the intensity. The condition of affairs in this country 100,000 deaths from plague taking place in one wee the British Isles as the climax of an epidemic which in course of five months had destroyed 800,000 of its pe would be similar to that now existing in the Punjab at present time. The state of mind of the rest of the inh tants of Great Britain and Ireland under such a catastr coming on the top of a devastation which had previo destroyed over 2,000,000 would not be one of calmness contentment. In the first 12 weeks of the year there 145,000 deaths from plague in the Punjab; in the next weeks 286,700 deaths. During these six weeks the pl deaths were as follows:—

Week ending	April	6th	... ...	34,651 deaths.
"	"	13th	... ...	39,084 "
"	"	20th	... ...	47,047 "
"	"	27th	... ...	54,204 "
"	May	4th	... ...	51,305 "
"	"	11th	... ...	60,400 "

These facts will dispel the view that the plague is a sm thing in India scattered over a vast continent. The ef in the Punjab may be gathered from the following ext from the *Times of India* of June 1st, 1907:—

> A picture of some of the results of the terrible epidemic in Punjab is given by the "Statesman's" Simla correspondent. To dis this epidemic (he writes) with the statement that the people of Punjab have been dying from it for some time past at the rate of 50 a week gives but a faint idea of the deserted villages, the crops rot upon the ground over wide areas for lack of men to reap them, and breaking up of homes and family life inseparable from such a calam The people have learnt to quit their villages and to camp out in the when the disease appears and the worst is now over for the year, the hot winds of May invariably reduce the mortality. But the has attained such extraordinary magnitude that it is affecting whole outlook of the people. In Simla carpenters have become diff to procure, because the Jullundur district, where most of them li has suffered so terribly. The plague is an undoubted factor, tho perhaps not the principal one, in connexion with the much-discu unrest. It is also becoming important in changing the relat between population and sustenance, since the survivors inherit property of those who succumb and grow less inclined in conseque to work for themselves.

In another extract from the same paper it is stated t "natives of Rawalpindi who have relations in the plag infected villages will not go to tend their sick; others h left the corpses or belongings of deceased relatives to mercy of the village rather than risk plague. Firewood not obtainable to burn the dead, so timber from the houses being utilised and many Hindus are burying their dea This last is against the religious views of the Hindus, their necessity has brought it about.

The concentration in the Punjab does not mean an eq distribution of the disease over the whole province. T mortality falls with unequal intensity on the divisions a districts into which the province is divided.

Table I. gives the deaths registered in the rural circles the Punjab with the death-rates of each from 1901 to 19 inclusive. The statistics are not available for the gre epidemic of 1907 or for the lesser one of 1906, but tho which are available show the great incidence of plague certain rural areas. In 1902 the district of Ludhiana w worst affected and had a death-rate from plague of over per 1000. More than a fourth of the deaths in the ru circles occurred in this circle. Umballa came next with per 1000 and Sialkot with 26 per 1000; one-third of t circles were not infected. In 1903 Gujranwala was t worst infected circle and had a death-rate from plague of per 1000; Amritsar and Jullundur came next with mortality of 30 per 1000 each; seven circles still remain unattacked. In 1904 only one circle remained free from t disease. Shahpur had a death-rate from plague of 74 p 1000 of its inhabitants, Sialkot 48 per 1000, Gurdaspur 46 p 1000, Ludhiana 45 per 1000, Gujrat 41 per 1000, a Jullundur 35 per 1000. In 1905 the recurrence in the ru circles was not quite so severe as in 1904, still Rohtak had death-rate from plague of 52 per 1000, Gurgaon 40 per 100 and Ludhiana 34 per 1000. Similar rates are to be noted the towns of the Punjab. For instance, in 1902 Rupar,

SIR WILLIAM TENNANT GAIRDNER, K.C.B., M.D.
(From a photograph by Messrs. Elliott and Fry.)

of Shahpur as a whole, it is safe to say that similar rates of 20 and 40 per cent. occurred in some of the villages as were recorded two years previously in the villages of Ludhiana. There was in 1904 an abnormal increase in the total urban death-rate which the Sanitary Commissioner states was accounted for by plague, and he mentions the high rate of 145 per 1000 in Hodal in the Gurgaon district and of 125 per 1000 in Miani in the Shahpur district, whose death-rate from plague was 100 per 1000 in each case.

If the totals for the five years in the rural circles be taken it will be seen that the Ludhiana district lost 100,000 of its inhabitants out of 586,000, or more than 1 in 6. Sialkot lost 103,000 out of 994,000, or nearly 1 out of every 9. Gujranwala lost 101,000, or nearly 1 in 8 of its population. I have not been able to add to these losses in the rural districts those of 1906, which was a comparatively light year, and those of 1907, which has been worse than any of the previous years, but the figures as they stand demonstrate a devastation on an immense scale, and which with the losses of 1906 and 1907, together with what is to come, means a mortality comparable with even that of the Black Death.

Though not able to give the statistics of the rural circles for 1906 and the earlier months of 1907, I am able to give them for the divisions and districts of the Punjab as a whole from the year 1901 to May 11th, 1907. There are five divisions in the British territory of the Punjab Province. These divisions contain a population of 20,000,000. Since 1901 they have lost 1,500,000 of their inhabitants—i.e., more than one-fourteenth of their total population. The Jullundur and Lahore divisions have suffered the most. Jullundur has lost 441,000 of its inhabitants out of 4,260,000—i.e., more than one-tenth; and Lahore has lost 665,000 out of 5,550,000, or nearly one-eighth. In these two divisions the incidence on some of the districts was very heavy; thus the district of Ludhiana has lost 140,000 out of 673,000 of its inhabitants, which is more than one-fifth of its population; another district of Gujranwala has lost 156,000 of its inhabitants out of 890,000, or slightly less than one-fifth of its population.

There are 29 districts in the Punjab and eight districts have lost less than 1 per cent. of their population, seven districts under 5 per cent. of their population, three districts over 5 and under 10 per cent. of their population, nine districts over 10 and under 15 per cent. of their population, and two districts have lost 17 and 20 per cent. of their population. The map shows the distribution of this mortality and its incidence in percentages of the population. With the districts as a whole giving such figures it is certain, owing to the fact that plague is never evenly distributed, that some of the villages have lost half their population.

THE PREVENTION OF PLAGUE IN INDIA THE MOST IMPORTANT QUESTION FOR INDIA AND ENGLAND AT THE PRESENT TIME.

The disease attacks the able-bodied and the strong, the bread-winners and protectors of the family. It is the sturdy peasants of the Punjab, the sowers and tillers of the soil, the producers, that are dying in such enormous numbers, and if they continue to die the effect, as has been the case in all epidemics, will be a serious disorganisation of the social and economic conditions of the province. Already in 1903 the Lieutenant-Governor of the province recorded that there had been an increase of crime and although the effects of the plague had not been immediately apparent he anticipated that trade, agriculture, and education, recruiting and other interests were bound to suffer. These anticipations and more have happened and the state of the Punjab has become socially and politically a serious cause of anxiety. It has recently been announced in the *Times* that there is a deficit of 18 lacs of rupees in the Punjab revenues of last year and that in many places the crops are standing unreaped because there are no harvesters. The silence of those unharvested fields, together with the figures of mortality, should bring to everyone's imagination a very clear realisation of the awful devastation of the Punjab. Nor are the effects likely to be confined to the Punjab, for there can be no moral and material progress of India as a whole when one of its smaller provinces is being more than decimated, and when there is danger of the disease attacking other provinces with a similar intensity.

It will be recognised from the foregoing facts that the dying millions in India present a problem of the greatest urgency and danger. The plague if left as it has been within recent years to take its own course bids fair in such circumstances to overwhelm not only India but also to be danger to the world.

MODES OF DISSEMINATION AND CHANNELS OF INFECTIO

Turning to the preventive aspects of plague the questio arises, Are the principal modes of dissemination and th channels of infection known? It is now accepted that th importation of plague into a healthy locality can be effecte by an infected human being, or an infected rat, or infecte clothes. Observations have been so numerous as regard these agencies as to remove all doubt on this point. Dr. E. E Klein has further shown by some important experiments tha infected grain may also be an agent in the importation o the disease. By feeding rats and guinea-pigs with grai which had been contaminated with old cultures of plague and which was then dried, he was able to cause plague i those animals, so that grain which has been infected wit infective material from plague rats or human beings may on importation into a healthy seaport, give plague to health rats on shore which eat the contaminated portions of the grain. The association of corn ships with plague is a very old one. In recent years the association has been ascribed almost wholly to plague rats on board ship which have left the ship and infected healthy rats on shore, but now infected grain must be added as a likely agent.

Once imported, the dissemination of the disease is effected by similar agents as those bringing about importation. Rats, clothes, human agency, and food play their respective parts. It is now almost universally admitted that, except in pneumonic cases, rats are the principal agents in the dissemination of the disease, though personal contact, as in typhoid fever, also plays its part. They bring the infection into houses connected with their subterranean passages. In Hong Kong one could trace many of the subterranean passages with their infected rats and their connexion with the distribution of the disease in the houses. A systematic bacteriological examination of rats trapped and found dead proved that plague in the rats of the locality preceded plague in man. So constantly did this occur that as soon as plague-infected rats were discovered measures were introduced as in Cape Town but on a more extended and systematic basis, of treating the house or locality as plague infected. In other words, a policy of forestalling plague was adopted. The precedence of rat plague in relation to plague epidemics was observed in Bombay, the Punjab, Calcutta, South Africa, Australia, and Southern China. The value of the Hong-Kong observations lay in the direct evidence obtained by scientific and precise methods not only of the direct relationship which the precedence of rat plague bore to human plague but also of the important rôle which the rat plays in the spread of the disease from house to house and in groups of houses. Similar observations were made by Dr. J. Ashburton Thompson in Sydney, but under different conditions. The Sydney outbreaks are comparatively mild, the mortality being under 40 per cent., and consist mainly of bubonic cases with but few septicæmic cases. Probably the type in Sydney was the same as that met with in Cape Town, where one of the marked features was absence of cerebral symptoms and intestinal disorders, differing in this respect from the type met with in Poona in 1897, but which in 1907 seemed to me to have changed, presenting fewer nervous symptoms. The Hong-Kong outbreaks are exceptionally virulent, the mortality being over 80 and 90 per cent. and with a large percentage of septicæmic cases.

The problem of the dissemination of the disease by rats is not solved by simply proving that rats are infected with plague in a house or locality before human beings, or by the fact that if measures are taken to dispose of the infected rats human plague will not occur, and, *vice versâ*, if no measures are taken plague will attack some of the inmates of the house. The question naturally arises, How is the infection of the rat transferred to man? There are two views and the upholders of each have a tendency to claim that theirs is the only way. The more that is learnt of plague the more it is evident that there is no only way.

THE FLEA THEORY.

Dr. Ashburton Thompson had exceptional opportunities of studying the small outbreaks in Sydney and on that study he came to the conclusion that Simond's theory that the flea on the rat, leaving the rat dead from plague and then biting man, transfers plague from the rat to man, explained the phenomena connected with plague. That theory, of which

Gairdner adopted the plan of withholding alcoholic stimulants from his younger patients suffering from typhus fever and giving it in very moderate doses to only a small percentage of the adult cases that were under his care at Glasgow. The result was that his total mortality was for all cases 11·93 per cent., whilst amongst the King's College Hospital patients it was, according to Murchison, 25 per cent.; the latter institution lost 17 per cent. of the youngest patients, and for the same age Gairdner's percentage mortality was less than 1. He insisted on the utility of milk in the treatment of the disease and there is no doubt that his conclusive demonstration that the rôle of alcoholic stimulants was not that of a specific remedy but rather that of an occasional therapeutic aid did much to convert the profession from the exaggerated view that was then held about its value. We have said enough of his scientific writings to show that he was a man who has left his mark on the thought of his age and materially contributed to the progress of medicine.

We have received the following appreciation of Sir William Gairdner from Dr. J. G. Glover, a friend of the distinguished physician:—

"It has been my privilege to enjoy the friendship of Sir William Gairdner for 40 years. I have known him longer even than that. My earliest recollection of him was in the Edinburgh University days of the 'fifties,' in which his familiar figure and energy were much in evidence as pathologist, succeeding Dr. Bennett. In the year 1866, in Glasgow, I had occasion to consult him, then professor of medicine in the University of Glasgow, in regard to a disease in the knowledge and treatment of which he was a master—typhus fever. The patient was a relative and I found Gairdner not only a master but a sympathetic friend who gave me the most valued help and saw me safely through my anxiety. This was a historical time in the sanitation of Glasgow. Its sickness, and especially its perpetual harbouring of typhus fever, had become a scandal and a discredit. Fortunately, Gairdner had become its medical officer of health and under his great lead there was well begun the work of clearing large areas of the city by razing to the ground the hopelessly infected and insanitary property which served as a centre and focus of disease extending far beyond its own immediate neighbourhood. Dr. Gairdner kindly took me round the city and showed me the work both of destruction and construction in process with obvious pride, enunciating the large principles upon which such work has to be done by municipalities to make cities wholesome and worthy of Christian civilisation. The work was most congenial to him and it may be doubted whether any other was ever more so, although he took it up originally with some demur, as being likely to sever him from clinical pursuits. He persevered with it for ten years and only abandoned it when the duties of the University and his consulting practice compelled him to do so. But his interest in its continuance never flagged and almost the latest letter I had from him was an enthusiastic eulogy of the 'Memorial Volume of the Writings'[1] of his great successor, Dr. J. B. Russell, which he described as 'a monument to a very admirable man for whom I have the greatest possible affection.' If there was any other work which Gairdner loved more than the transformation of a sickly and infected city into a comparatively healthy one it was the work of medical education. As theorist and in practice, as professor or as clinician, he was enthusiastic to the last as a teacher of medicine. Whether in the post-mortem theatre or in the hospital ward, or at a medical society, or in the chair of the British Association, his zeal and his cheerful optimism raised all his work to a kind of worship—'ever as in the Great Taskmaster's eye.' His interest in getting to know all that was knowable amounted to a passion and kept him a student to the last everywhere. He only relinquished his chair of medicine when blindness in part had overtaken him and physical power to keep pace with the leaps and bounds of medicine failed him. It would not surprise me to learn that the study of his own grave disease and the attempt to get medical lessons from its behaviour served partly to entertain his last years. Perhaps therapeutical medicine was not his strongest point, though he always resented being supposed to have a narrow prejudice against the employment of all drugs. But he did one masterpiece of negative work in this field: he destroyed the pernicious doctrine of Todd, which would add alcoholic intoxication to the intoxication of typhus and of pneumonia. And one of the best things that any student of medicine can do is to buy his book, 'The Physician and Naturalist,' and read it through and read twice the chapter on 'Facts and Conclusions as to the Use of Alcoholic Stimulants in Typhus Fever' and the three subsequent chapters. I have spoken of Sir William Gairdner as a friend. But Sir William Gairdner had no enemies. He was as much at home in Glasgow as in Edinburgh, and in London, Paris, or Rome as in Scotland. By his death the profession loses one of its greatest, cheerfullest, devoutest members."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Buliguinski, professor of medical chemistry in the University of Moscow.—Dr. Giuseppe Corradi, formerly professor of surgery in the Florence Medical School.—Dr. Cannieu, professor of anatomy in the University of Bordeaux.

Medical News.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part II., Surgery.—William Pearson, Robert E. Wright, Richard G. S. Gregg, and Allman J. Powell (passed on high marks), William E. M. Armstrong, Frederick Stevenson, Henry de C. Dillon, Oliver St. J. Gogarty, Thomas B. W. MacQuaide, Reginald Holmes, Wallace D. Mitchell, James C. C. Hogan, Madeleine S. Baker, Charles H. O'Rorke, James E. M'Farlane, Joseph C. Ridgway, and William A. R. Spong.

Part II., Midwifery.—Frank R. Seymour, Henry de C. Dillon, William A. R. Spong, William E. M. Armstrong, Robert de C. Wheeler, Arthur E. Knapp, Thomas P. Dowley, John H. Waterhouse, and Alfred H. Smith.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Bernard G. Quinlan, Ronald G. M'Entire, Henry L. W. Woodroffe, Patrick Murphy, James M. Elliott, Thomas G. Harpur, Arthur Chance, Edgar Ll. F. Nash, Thomas L. Bookey, Francis C. Crosslé, Arthur F. Shaw, Leonard Shiel, Oswald C. Tandy, Edward H. H. Lloyd-Dodd, Francis Breen, Albert E. Malone, George M. Maybury, Robert W. Murphy, Hugh E. Williams, Hugh M'C. Fleming, Matthew M'Knight, James C. Kelly, Andreas A. Louw, Robert C. M'Kelly, and Humphry L. Blackley.

Botany and Zoology.—Henry L. W. Woodroffe, Arthur F. Shaw, Francis C. Crosslé, Thomas G. Harpur, Georgina Revington, Hubert T. Bates, Eileen M. Hewitt, Frederick B. M'Carter, Gerald G. P. Beckett, Dorothy K. Milne, Francis Usher, Percy D. Long, Robert W. Murphy, John T. Higgins, Thomas King-Edwards, Henry S. Campion, Arthur Chance, Marjory Chapman, Francis T. G. Corscadden, Richard Grandy, Richard P. Pollard, James N. G. Nolan, Cecil Rutherford, Brian D. Crichton, Bernard G. Quinlan, and Robert G. Ball.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Felix Klemperer, *privat-docent* of Medicine and Laryngology, and Dr. Johann Ziemann, an eminent naval surgeon, have been granted the title of Professor.—*Bordeaux:* Dr. Mandoul has been appointed Professor *agrégé* of Natural History.—*Freiburg:* Dr. Karl Hirsch of Leipsic has been appointed Professor of Medicine in succession to the late Dr. Louis Thomas.—*Lille:* Dr. Ch. Dubois has been appointed Professor *agrégé* of Physiology.—*Montpellier:* Dr. Cabanes has been appointed Professor *agrégé* of Natural History.—*Nancy:* Dr. Collin has been appointed Professor *agrégé* of Anatomy.—*Paris:* Dr. Déjerine has been appointed Professor of Medical Pathology in succession to Dr. Hutinel, who has been appointed to the chair of Children's Diseases. Dr. Mulon has been appointed Professor *agrégé* of Anatomy and Dr. Brumpt Professor *agrégé* of Natural History.—*Prague (German University):* Dr. Oskar Fischer has been recognised as *privat-docent* of Psychiatry.—*Strasburg:* Dr. Otto Schirmer has been appointed Professor of Ophthalmology in succession to Dr. Laqueur, who retires. Dr. Heubner of Leipsic has been recognised as *privat-docent* of Pharmacology.—*Vienna:* Dr. Otto Chiari, Extraordinary Professor of Laryngology, has been promoted to an ordinary professorship.—*Würzburg:* Dr. Oskar Schultz, who has charge of the Chemico-Physiological Department, Dr. August Gürber, *privat-docent* of Physiology, Dr. Otto Rostoski, *privat-docent* of Medicine, and Dr. Ludwig Burkhardt, *privat-docent* of agent in the dissemination of the disease in rats and possibly in other animals.

---

[1] Maclehose, Glasgow.

There is much in favour of Pulex cheopis playing an active part in the transfer of plague from the rat to man. There can be no doubt that Pulex cheopis, unlike Pulex fasciatus, another common rat flea, bites man. Pulex cheopis is only found occasionally in ordinary circumstances on man. As a rule, it is either the human flea or Pulex canis that is usually found on man. Hilger identified 59 per cent. of over 2000 fleas which he found on man as being Pulex canis, and it may possibly have been this flea which, owing to its wide distribution on rats, dogs, cats, and man, gave rise to the older views that dogs, cats, and fowls from infected houses spread plague even when these animals were unaffected. In certain circumstances Pulex cheopis may be found in numbers on man, such as the instance given by Liston, in which 46 per cent. of the fleas found on the persons of inmates in an infected house proved to be Pulex cheopis.

In Hong-Kong in 1902 I was able to infect two monkeys by placing rats which had died from plague and which were covered with fleas in the same cages as the monkeys but in compartments which prevented any possible contact between rat and monkey but which allowed of a free passage of fleas from rat to monkey. Both monkeys fell ill but recovered. The Indian Plague Commission has in a similar fashion on two occasions succeeded in transferring the plague of the rat to monkeys by the agency of fleas. As it is in the monkey so probably it is the case in man. No direct experiments can be made to prove this, but the accidental infection in man caused by the handling of rats dead from plague and on which Simond's first founded his theory would appear to bear the interpretation given them by the laboratory experiments.

On the other hand, taking the most liberal interpretation of the flea theory based on the experiments mentioned, it is doubtful whether the flea theory will account for more than a certain percentage of the fatal bubonic cases which may vary in different circumstances in different localities. Out of ten experiments with monkeys by the Indian Plague Commission eight failed and in my own experiments the monkeys recovered. Moreover, the fact that infants under one year of age are more or less immune to plague militates against the flea being as important an agent in the causation of human plague as of rat plague. The incidence on infants is very small. This has been shown by Lieutenant-Colonel C. J. Bamber, I.M.S., in the different Punjab epidemics. This immunity is shared with the aged. Fleas probably are not attracted to old people but the same cannot be said with reference to infants who sit, lie on, and crawl about the floor. The food of infants fed as a rule at the breast of the mother differs from that of the adults in that it is pure and not subject to contamination with plague virus and herein probably lies the explanation of the immunity of the infant.

THE FOOD THEORY.

The difference in the type of the disease in Sydney as contrasted with Poona and Hong-Kong has already been mentioned. More post-mortem examinations are made on plague cases in Hong-Kong than in any other part of the world, and it is on the observations there both on man and animals that the theory has been formulated that the ingestion of food contaminated with the plague virus is the cause of septicæmic cases of plague.

Wilm in 1896 found that in 20 per cent. out of 150 necropsies the mucous membrane of the stomach or intestines showed lesions with hæmorrhages, and he was successful in causing plague in fowls by feeding them with plague material and with pure cultures of the plague bacillus. He also succeeded in infecting a pig fed with the spleen of a man who had died from plague. In 1897 the German Commission in Bombay was successful in causing plague in rats, a mongoose, a squirrel, and monkeys by feeding experiments, but failed with mice, guinea-pigs, dogs, and pigs. The Austrian Commission was successful in similar experiments with guinea-pigs, rats, mice, and cats, but failed with dogs, pigeons, hens, and a mongoose.

In 1902 I had the opportunity of seeing with Dr. W. Hunter a large number of necropsies on plague cases in Hong-Kong and we were able to confirm the great frequency with which the intestines are the seat of primary hæmorrhagic lesions and the mesenteric glands swollen and hæmorrhagic. Later Dr. Hunter has given a detailed description of the pathological changes which are observed in the alimentary canal and which are practically present in all t septicæmic cases of plague. The stomach shows well-mark congestions and hæmorrhages; some of the hæmorrhages m occasionally be of the size of a dollar piece. The chang met with in the small intestines are even more severe th those in the stomach. Petechial hæmorrhages and blo extravasations with necroses, forming not infrequent superficial ulcers, are common. Peyer's patches and t solitary follicles are swollen and may be hæmorrhagic, a in some parts inflammatory changes extend through the wal of the intestine. The mesentery is frequently affected extensive hæmorrhages and the contained lymphatic glan are enlarged and hæmorrhagic. The lymphatic glan standing in relation to the ileum and cæcum are almo always affected. They are frequently double their ordina size and on section are œdematous, with minute blood e travasations into their parenchyma. With Dr. Hunter an Dr. Matsuda, a Japanese medical man lent to the Goven ment of Hong-Kong by Japan, I was able to car out a series of feeding experiments which establishe that poultry, calves, pigs, sheep, rats, and a monke contracted plague by feeding. We failed to caus plague in dogs by feeding. These observations on me and on animals led me to the conclusion that septicæmi plague is in most cases contracted by the alimentar canal; an additional fact which lends support to this vie is the frequency of abrasions and denudations of th alimentary canal in Asiatics. Dr. H. Fraser, who is engage in a research on the condition of the intestines, showed m in his laboratory at Kuala Lumpur in the Malay State microscopical specimens of the intestines of Chinese an Indians in which he had found over 50 per cent. wit abrasions or ulcers. Dr. Hunter has also shown that whe premonitory symptoms of plague do manifest themselves th patients frequently suffer from gastric and intestinal disorders with diarrhœa and in these cases examination of th blood shows a septicæmic infection.

More decisive than even the foregoing experiments o animals are those made by Dr. Klein in this countr because of the convincing histological work which he ha associated with them. He has proved beyond all question o dispute that the plague bacilli taken in contaminated food multiply while the food is in the intestines, enter through the lymph channels or lacteals of the intestines, and invade the blood in swarms. The only qualification is that the microbes shall be so protected as not to be affected by the gastric juice.

THE MOST FREQUENT HERNIA IN CHILDHOOD AND ITS SIGNIFICANCE.[1]

BY EDRED M. CORNER, M.A., M.C. CANTAB., B.SC. LOND., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS TO THE CHILDREN'S HOSPITAL, GREAT ORMOND-STREET, AND TO ST. THOMAS'S HOSPITAL.

IN February, 1904, I delivered a lecture at the Children's Hospital, Great Ormond-street, on the Pathology and Treatment of the Herniæ of Children and their Relation to Similar Conditions in the Adult.[2] At the time of its publication, some months after its delivery, I had other work in hand which would assist in the exposition of my view that the majority of herniæ in children were acquired and not congenital. The publication of these observations has been delayed until the present lecture.

If one turns to the work of those who regard these herniæ as being of congenital origin, and therefore often requiring active surgical interference, it is obvious that they take as the standard of their authority the fact that they have performed so many tens or hundreds of operations for the condition; indeed, it is usually stated in the early paragraphs of their papers. This is a very narrow point of view. The problems of the origination of herniæ in children cannot be settled only by observations made at the operating table. Careful notes and records in the out-patient room must come first and the results obtained in this way must be examined in the operating theatre. It will then be found that there is a close relationship between the conditions of the parts noted in the theatre and certain facts in the clinical history empowered to provide a second sanatorium at a cost not exceeding £6000," which was carried. Mr. Thompson promised £100 to the fund for the purpose and thought that a second sanatorium was greatly needed and would enable the men to be treated in one and the women and children in the other. The election of officers for the year and a vote of thanks to the chairman concluded the meeting.

[1] Part of a clinical lecture delivered at St. Thomas's Hospital.

[2] THE LANCET, August 20th, 1904, p. 511.

LITERARY INTELLIGENCE.—Messrs. Hutchinson and Co., Paternoster-row, London, E.C., will shortly publish, at the price of 2*s*. 6*d*. a new book by the author of the "Soul Market," entitled "Baby Toilers," the objects of which are to enlist public sympathy in the question of sweated labour and to help towards the introduction of a minimum wages Bill for home workers.

MEDICAL AFFAIRS IN ASHANTI.—It appears from the annual report of the Colonial Office, just presented to Parliament, that during 1906 the medical staff of Ashanti consisted of a senior medical officer and five medical officers. The department was successively in charge of Mr. G. J. Rutherford, Mr. T. E. Rice, and Dr. J. O. Montgomery. The average European population during 1906 was 383; of these 48 were officials and 335 non-officials. During the year six deaths occurred—all among non-officials—representing a European death-rate of 15 per 1000. Five officials and 24 non-officials were invalided, an invaliding rate of 75 per 1000. A death-rate of 15 per 1000 is not excessive for West Africa, and on the whole the health of the Europeans in Ashanti may be described as fair. There are no statistics available to calculate the health of the native population, but there were no epidemics and therefore it would appear to have been normal. At the Native Hospital 755 in-patients were admitted, of whom 20 died. In the out-patient department 8485 new cases were treated. During the year vaccination was systematically practised. A European hospital, containing four wards, is in course of construction. Permanent latrine houses, constructed of corrugated iron and concrete, have now been erected in the town of Kumasi. The water-supply is good and plentiful. A number of new wells have been constructed and alterations have been made in some of the old ones.

THE BRITISH ANTARCTIC EXPEDITION.—An exhibition of medical and scientific interest was opened at 5, Regent-street (close to Waterloo-place), London, S.W., on July 1st, in connexion with the expedition which, under Lieutenant Shackleton, will shortly leave this country for southern seas. The exhibition is divided into two sections, the one dealing with food and the other with equipment. Among the firms in the first section who have exhibits are Messrs. Coleman (Norwich) who, in addition to other gifts, have supplied five tons of flour for use in the expedition, and Messrs. Rowntree (York) who have given a large quantity of chocolate and cocoa. This firm has added to the interest of the exhibit by showing botanical specimens of the cocoa plant and the cocoa in different stages of manufacture. Messrs. Bird (4B, Upper Thames-street, London, E.C.) have presented the expedition with custard powder; the Imperial Dry Milk Company (agents, Messrs. Joseph Nathan and Co.) with dried milk; the Oxo Company (4, Lloyd's-avenue, London, E.C.) with Oxo; and the Montserrat Company with 17 cases of lime-juice. All these firms have exhibits of interest. Other firms supplying the expedition with food are the International Plasmon Company, Limited (66A, Farringdon-street, London, E.C.); the McDoddie Viands Company (155A, King's-street, Hammersmith, London, W.); Messrs. Brand and Co. (74–84, South Lambeth-road, London, S.E.); Bovril, Limited (152, Old-street, London, E.C.), who send their emergency food and rations, including Pemican and Virol; and Messrs. Griffiths McAlister (Manesty's-lane, Liverpool) who supply hams, bacon, tinned fish, and jams. The Remington Typewriter Company (Gracechurch-street, London, E.C.) supply a typewriter and Messrs. Guttman and Co. (8, Long-lane, London, E.C.) Thermos flasks. Messrs. Burroughs, Wellcome and Co. (Snow-hill, London, E.C.) furnish the medical supplies and photographic outfits. A noticeable feature in the equipment section is the absence of any large display of furs. It has been found that Jaeger and waterproof clothing are more suitable material for body coverings in Polar regions and consequently fur is practically only used for boots (Finskoo) and mittens. The Jaeger Company are supplying the wool clothing and Messrs. Burberry (30 and 31, Haym[illegible]n, W.) the waterproof clothing. The hut for use by the expedition party (a sketch of which is shown) has been made by Messrs. Humphrey. It is constructed of wood, with double walls packed with granulated cork, and measures 19 feet by 33 feet. It will be lighted with acetylene gas. The generator has been supplied by Messrs. J. and J. Drummond (Aberdeen). The cooking apparatus to be carried on the sledges is the one invented by Dr. Nansen, the heat being generated by a Primus oil-stove. In addition to examples of the furniture for use on the expedition and tool outfits there is a tableau representing an exploring party with a completely equipped sledge and tent. The exhibition will close at the end of next week.

THE CANCER HOSPITAL.—In the grounds of this hospital a conversazione was held on July 2nd, when the president of the hospital, Lord Ludlow, who was accompanied by Lady Ludlow, received the guests. In the course of the evening an inspection of the wards took place. The hospital, which was founded in 1851 by the late Dr. William Marsden, received during the past year 817 in-patients and treated 17,376 out-patients. The institution is solely dependent on voluntary support and funds are urgently needed to meet an increasing expenditure. Every year it is found necessary to draw more and more on capital. Last year the ordinary income amounted to £9013 and the expenditure to £16,699, making a deficit of £7686.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—The annual general meeting of this association was held at the Trocadéro, Piccadilly-circus, London, W., on June 27th, Surgeon-General G. J. H. Evatt, C.B., President of the association, being in the chair. The report of the council and balance sheet for the last year were duly presented and unanimously adopted. The financial condition was considered very satisfactory, and it was decided to invest another £100 in Consols. The officers and council for the last year were re-elected with the exception of the treasurer, Dr. W. Gayton, who desired to retire from that office. Mr. A. A. Napper was unanimously elected treasurer in his place, and the thanks of the association were given to Dr. Gayton for his long and able services in the past. Afterwards the members and their friends dined together. A musical entertainment was given by Mr. T. F. Noakes and a very pleasant evening was spent.

MILK CONTAMINATION AND DISTRIBUTION.—A conference on this subject was held at the Incorporated Institute of Hygiene, 34, Devonshire-street, London, W., on July 1st. Mr. A. W. Mayo Robson, who presided, said that milk was a necessary food not only for the child but for the adult. Infected milk was the cause of a large infantile mortality and of many physical disabilities in children. Those who escaped death often became degenerate and drifted into our hospitals, asylums, and prisons. Dr. J. C. Thresh proposed a motion, which was subsequently carried, to the effect that the periodical veterinary inspection of all cows kept for the purpose of giving milk for human consumption should be made compulsory throughout the United Kingdom. Veterinary inspectors should give their whole time to the matter, he said, and be free from local influence. Such inspection should take place periodically four times a year and power should be given to the inspectors to visit places where cows are kept at any time. Power ought to be given to inspectors to see that cowsheds were properly constructed and they should also have power to authorise the analysis of the water-supply. It was of little use providing facilities for cleanliness among the cowmen unless the men were properly educated. He had known cases where cowmen, after washing their hands, had entered the cowshed and taken up a milking-stool bespattered with manure. The only remedy was to bring the men into a police court occasionally. Many medical officers of health were now of opinion that another source of milk contamination was the way in which milk was stored by the consumer. He was of the opinion, however, that if the public could depend upon the purity of milk the demand for it would greatly increase. Dr. George Carpenter put forward a long series of proposals dealing amongst other things with annual licences and microscopical and bacteriological examination of milk, most of which did not meet with the approval of the meeting. He believed that the best interests of the community would be served in the matter of a pure milk-supply if the Local Government Board were made the chief authority to deal with the matter. He drew a harrowing picture of some of

TABLE II.—*Incidence of a Median Ventral Hernia between the Divaricated Recti at Different Ages.*

1	30 0	per cent. had ventral herniæ.
2	62 7	„ „ „
3	50 0	„ „ „
4	47·8	„ „ „
5	43·5	„ „ „
6	40·2	„ „ „
7	30·9	„ „ „
8	28·8	„ „ „
9	17·7	„ „ „
10	20·0	„ „ „
11	17·3	„ „ „
12	11·8	„ „ „
13 } 14 }	6·7	„ „ „

This table shows that the frequency of the median ventral hernia increases steadily from birth to attain its maximum in the second year of life, whence it falls steadily until adult life is reached, when it is rarely seen.

Therefore, it would appear that a median ventral hernia between the divaricated recti is an acquired character which becomes spontaneously cured as growth takes place. Its significance in connexion with the formation of inguinal hernia is enormous. If one sees a house on fire and finds one storey alight it is natural to conclude that some incident has occurred which originated the fire. But if one finds two, three, or more storeys alight one concludes that they arose from one common cause and not that there were two, three or more simultaneous fires kindled. Hence, if we find multiple herniæ as in the first table, at least we may suspect that they have a common causation, though there is no proof that they are not all of congenital origin. But when in addition they are combined with a median ventral hernia between the divaricated recti, as in Table III. an acquired character known to be due to the raised intra-abdominal pressure, the probability is greater that they have a common and a similar origin. Thus this form of ventral hernia becomes an indication of extreme etiological importance. In the third table is represented the percentage in which the presence of this ventral hernia was found at the different ages.

TABLE III.—*Second Series of 2600 Observations.*

	Per cent.
Herniæ present in all cases	32·7
Right inguinal hernia	4·2
Right inguinal hernia and median ventral hernia between the *divaricated recti*	4·7
Right inguinal and umbilical herniæ	0·8
Right inguinal and umbilical herniæ and median ventral *hernia through* the divaricated recti	2 3
Left inguinal herniæ	1·3
Left inguinal herniæ and median ventral hernia through the divaricated recti	2·1
Left inguinal and umbilical herniæ	0 4
Left inguinal and umbilical herniæ and median ventral through the divaricated recti	0 5
Umbilical herniæ	4·2
Umbilical herniæ and median ventral hernia through the divaricated recti	13·3
Median ventral hernia between the divaricated recti... ...	61·3
Right and left inguinal herniæ	1·0
Right and left inguinal herniæ and median ventral hernia through the divaricated recti	1·4
Right and left inguinal and umbilical herniæ	0·1
Right and left inguinal and umbilical herniæ and median ventral hernia through the divaricated recti	1·5
Epigastric herniæ	0·9

The median ventral hernia was found by itself in 61·3 per cent. of the *cases* of hernia; and when in combination also, in 87·1 per cent., a very *strong* indication of the probable origin of a very large number of the concomitant inguinal hernia; and, as the congenital causation of them in certain *cases* is *not* disputed, of the composite, not simple, causation of herniæ. This is strikingly brought out by the following figures, which represent the percentage proportions amongst the various herniæ found. In Table V. the herniæ, *accompanied* by the median ventral hernia between the divaricated recti, are just twice as large as when unaccompanied, a fact which would suggest that pressure herniæ (i.e., acquired) are twice as common as herniæ of congenital origin.

TABLE IV.—*From Second Series.*

	Per cent.
Of all the 2600 *cases herniæ were found in*	32·7
Median ventral hernia through the divaricated recti (with and without other herniæ)	24·21
Herniæ other than those between the divaricated recti ..	15 4
Herniæ unaccompanied by one between the divaricated recti	4·62

TABLE V.—*Of the Herniæ Themselves.*

	Per cent.
Herniæ accompanied by a median ventral hernia through the divaricated recti	25·8
Herniæ unaccompanied by a median ventral hernia through the divaricated recti	12·9
A *median* ventral hernia through divarication of the *recti; present alone*	61·3
A median ventral hernia through divarication of the recti; *alone* and with *other* herniæ	87 1

Every variety of hernia is more common when associated with another between the divaricated recti than when alone or associated with another variety of hernia. There are two main theories of hernia formation: one, ably and vigorously advocated by many surgeons, amongst whom may be mentioned Mr. H. J. Stiles of Edinburgh, Mr. E. W. Scott Carmichael of Edinbugh, Mr. R. W. Murray of Liverpool, Mr. H. S. Clogg of London, and especially by Mr. R. Hamilton Russell of Melbourne who has named it the *saccular* theory, states that herniæ appear on account of the sac being formed during development; the second, I believe first suggested by Mr. W. Arbuthnot Lane in 1897 and amplified by me in 1904, in which it is argued that the majority of herniæ in children arise from the increased intra-abdominal pressure which results from the gas production of intestinal fermentation. On the latter theory the herniæ can be produced in either of two ways or a combination of both: first, the intra-abdominal pressure may protrude the hernia by direct pressure; secondly, and more commonly, the pressure acts indirectly by modifying the growth of the tissues, particularly in the weaker regions, facilitating the development of a hernia by direct pressure. By the indirect action on its growth the raised intra-abdominal pressure destroys the protective valvular action of the inguinal region, after which a hernia is formed. In very young children the valvular action *may* be rendered incompetent by the mere stretching of the soft growing tissues. Thus, the younger the child the shorter the time required for the development of a hernia. But the mere presence of a hernia in a child shortly after birth does not necessarily indicate its congenital origin; for instance, it is known, even with the tougher tissues of adults, that a hernia may appear in a few hours or days.

To recapitulate, a median ventral hernia between the upper parts of the divaricated recti is manifold the most common and characteristic hernia of childhood. It has never received its full due owing to the fact that surgeons have made more observations in the operating theatre than in the out-patient room and have, with few exceptions, never combined these two sets of observations. This median ventral hernia is almost invariably an acquired character and is directly related to the pressure of gases produced by intestinal fermentation. Any hernia or set of herniæ in any situation are more frequent when accompanied by it than when alone (Tables III. and V.). Hence clinical experience shows that raised intra-abdominal pressure is directly related to the frequency of inguinal herniæ and, it is suggested, probably also to *their initiation. It has been further suggested* that the true proportion of acquired to congenital herniæ is *about* 2 to 1 (Table V.).

In the face of the fact that it is nearly impossible to recognise and distinguish the funicular variety of the congenital hernia sac from the acquired sac at an operation and even perhaps at a necropsy, there can be *no certain* knowledge of the formation of herniæ in children. *Therefore* I would suggest that by means of *the recognition of the* presence and significance of the *median ventral hernia*, its frequency and associations, it is *possible* to introduce a strong probability into the *question*, which would seem to indicate that acquired herniæ are more common in children than those due to the presence *of a congenital* sac. This is not a mere academic question, as the treatment to be adopted must *depend* largely upon *its appreciation.*

Harley-street, W.

inquire into the ventilation of factories and workshops has been presented to Parliament. In its first report the committee dealt with the removal by general ventilation of the more ordinary impurities arising from the presence of persons and lights. The second report deals with the application of fans to factory ventilation in connexion more particularly with the removal of dust, fumes, steam, and other impurities associated with special manufacturing processes.

Sight Tests in the Mercantile Marine.

The Board of Trade's annual report on sight tests in the Mercantile Marine states that of the 61 candidates for certificates who failed in form vision during 1906 one was re-examined and passed, while of the 57 who failed in colour vision 15 were re-examined on appeal and of these nine passed and six were rejected.

HOUSE OF LORDS.

WEDNESDAY, JULY 3RD.

Medical Companies.

Lord HYLTON moved the third reading of the Prohibition of Medical Practice by Companies Bill, and his motion was agreed to without discussion.

His LORDSHIP then formally moved that the Bill should be passed.

The Earl of CREWE (President of the Council) said that at this stage he desired to move one or two amendments to the Bill. He had suggested to Lord Hylton, who had taken charge of the Bill in its progress through their lordships' House, that he should confer with his department on the subject of what amendments should be introduced into the Bill. The noble lord had been good enough to carry out that suggestion, and he understood he would agree to the amendments now about to be proposed. He (Lord Crewe) now proposed that whilst offending companies should still be liable to penalties for contravention of the provisions of the Bill, the directors, managers, and officers should only be liable if they knowingly and willingly authorised or permitted such contravention. He moved an amendment to make it plain that this was the intention of the Bill.

The amendment was agreed to without further discussion.

The Earl of CREWE then moved a further amendment to the effect that a "company" should be defined for the purposes of the Bill as "any body corporate wherever established which carries on business in the United Kingdom."

This important amendment was agreed to.

The Bill was then passed. As it originated in the House of Lords it has still to pass through all its stages in the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 26th.

The Report of a Medical Officer of Health.

Mr. WEIR asked the President of the Local Government Board whether he was aware that Dr. J. Lloyd Roberts of Colwyn Bay, county medical officer of health, when recently submitting his annual report at a meeting of the district council of St. Asaph, North Wales, was requested to amend it; and whether he would state if a local authority had the right to insist on a medical officer of health withdrawing statements which he had thought proper to make in his annual report in regard to the sanitary condition of a district under his supervision.—Mr. JOHN BURNS replied: I am informed that, in the opinion of the district council, the report was inaccurate and incomplete, and that the medical officer of health has been asked further to consider it and to submit it at the next meeting of the council. I am not fully acquainted with the circumstances of the present case but, speaking generally, it does not appear to me that a district council can insist on the withdrawal by the medical officer of health of statements in his annual report in regard to the sanitary condition of the district under his supervision.

The Boyle Sanitary Authority.

Mr. JAMES O'KELLY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the Local Government Board for Ireland had given notice that one of its inspectors would hold an inquiry on July 2nd, 1907, on a petition forwarded by certain ratepayers in Boyle to constitute that township an urban sanitary authority; whether he was aware that the notice was only received on June 19th, and that there was no meeting, either of the Roscommon county council or the Boyle district council, to be held between the date of notice being received and that on which the inquiry was to be held; whether, seeing that both these bodies were interested in the matter to be inquired into, he would see that the inquiry be adjourned to a date that would give these bodies an opportunity of considering the course they should adopt in the interests of the ratepayers they represented, and whether he would take steps to secure that the Local Government Board should consult these bodies as to a convenient date for the inquiry.—Mr. BIRRELL answered: The Local Government Board gave the usual statutory notice of this inquiry. The Board has since received from the county and rural district councils a request that the inquiry may be postponed and in reply has informed these bodies that the inspector will attend and open the inquiry on the date fixed and then adjourn it to any date which may be arranged to suit the convenience of the parties concerned.

The Chief District Medical Officer of Lewis.

Mr. WEIR asked the Secretary for Scotland, having regard to the fact that the Local Government Board for Scotland in its report last year expressed the opinion that it was not possible for the duties attaching to the office of chief district medical officer in the Island of Lewis to be discharged by anyone resident in Dingwall, whether he would state what steps had been taken by the Board to ensure the appointment, vacated some time since by Dr. C. M. Macrae, of Stornoway, being filled by a medical officer resident in the island.—Mr. SINCLAIR said in reply: I have no official information but I understand the district committee is to meet shortly in order to appoint a successor to Dr. Macrae.

Still-births in 1906.

Mr. WILLIAM PEARCE asked the President of the Local Government Board to give the number of still-births which were notified to the local supervising authorities by certified midwives under the Midwives Act, 1902, during the year 1906.—Mr. BURNS sent the following written answer: I have made inquiry but I have not been able to obtain this information for which the honourable gentleman asks.

The Qualifications of Irish Medical Officers of Health.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland what special training, if any, medical officers of health had got in veterinary matters and whether, seeing that by the Public Health Act they were expected to diagnose diseases in animals used for food of man, he would give instructions to all sanitary authorities that only veterinary surgeons should be employed in the inspection of meat and milch cows in all cases where the medical officer of health had no special training.—Mr. BIRRELL (in a written answer) replied: In the case of county boroughs any person who may be appointed as medical superintendent officer of health is required to possess a diploma in sanitary science, public health, or State medicine. This requirement ensures that the person appointed possesses the requisite training to enable him to discharge the duties which devolve upon him in the inspection of meat intended for human food. In other districts in which a superintendent medical officer of health is appointed the officer is required to possess a similar diploma. Any sanitary authority may appoint a veterinary surgeon for the purpose of the inspection of meat to be used for human food, and such appointments have been made in the case of Dublin and Belfast.

THURSDAY, JUNE 27TH.

The Investigation of Cancer.

Captain FABER asked the Prime Minister whether he could now state if he was able to appoint a Royal Commission to examine into the causes of the national scourge, cancer.—Sir HENRY CAMPBELL-BANNERMAN replied: Since the honourable and gallant Member gave notice of this question some little time ago I have made inquiries of the authorities who are best qualified to express an opinion on a matter which we must all feel to be of the utmost importance and I am advised that it would not be expedient at present to recommend the appointment of a Royal Commission to inquire into the causes of cancer. Though much research work is being systematically carried on in this country in connexion with the Imperial Cancer Research Fund and otherwise, and also abroad, I am advised that much remains to be done before any facts can be brought before a Royal Commission with any likelihood of their making such an inquiry fruitful for the public advantage.

Mr. A. LEE asked as a supplementary question whether the right honourable gentleman would consider the advisability of making a grant to the Imperial Cancer Research Fund.—Sir HENRY CAMPBELL-BANNERMAN replied that the question did not arise out of his answer.

Medical Officers of Dublin Unions.

Mr. CHARLES CRAIG asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that prior to the Local Government Act, 1898, the medical appointments in the North and South Dublin unions were held by an equal number of Protestants and Roman Catholics and that since the passing of that Act every vacancy occurring in the medical offices had been filled by a Roman Catholic, and whether the Government would take steps to secure fair treatment for Protestants.—Mr. BIRRELL replied: I am not aware whether the facts are as stated in the question. The Local Government Board has no information as to the religious belief of medical officers of unions whether appointed before or since the passing of the Local Government Act of 1898. In any event, the matter is not one in which the Government has power to interfere.

The Sanitary Condition of Piershill Barracks.

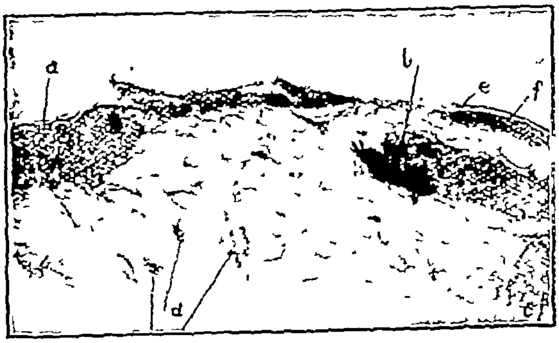
Mr. CHARLES PRICE asked the Secretary of State for War what were the dates upon which the first report was made as to the sanitary condition of Piershill barracks, and the report of the medical officer of health and the chief sanitary inspector for the city of Edinburgh; whether, subsequent to the latter report, another inquiry was made by the War Office; and, if so, whether such inquiry had been concluded, a report issued, and when.—Mr. HALDANE furnished the following written answer: The first report on the sanitary condition of Piershill barracks was made by the sanitary engineer of the War Office and the sanitary expert of the Army Medical Advisory Board in April, 1906. A second report was made by the Director-General, Army Medical Service, in May, 1906. A conjoint inspection was made by the sanitary engineer of the War Office and the sanitary expert of the Army Medical Advisory Board, on the one hand, and the medical officer of health of the borough of Edinburgh and the chief sanitary inspector, Dr. A. M. Williamson, on the other, in December, 1906, and a third report submitted by the two first-named officials. The report of the Director-General, Army Medical Service, and the report dated December, 1906, by the sanitary engineer of the War Office and the sanitary expert of the Army Medical Advisory Board, were laid before Parliament in 1906. There has been no subsequent inquiry later than that mentioned—viz., December, 1906.

An Accident at Perth Station.

Mr. JAMES O'CONNOR asked the Postmaster-General whether he was aware that an auxiliary postman met with an accident at Perth station on June 15th and that he was kept in the mail porters' office for over an hour before being taken to the hospital, owing to the fact that an ambulance could not be got and no one would take the responsibility of incurring an expense for cab fare, and whether he would issue instructions to see that such delay in cases of accident did not recur.—Mr. BUXTON replied (by written answer): I find that an auxiliary postman met with an accident to his foot at Perth station on June 15th and I am informed that he was assisted to the mail porters' room, where first aid was rendered by a member of the railway ambulance place pure connective tissue is left, as Juliusberg[5] and I[6] have found 12 weeks after the treatment with hydrochloric acid that microscopical examination shows the lupus tissue replaced by scar tissue with no remains of lupus foci (cf. Fig. 3). If after a few or many sittings all nodules have so far disappeared that none are to be seen either with the naked eye or with the diascope, or after injections of tuberculin, or in an excised piece of the tissue, then it is allowable to say that recovery is probable. (Instead of giving tuberculin injections Unna's method of rubbing in tuberculin soap may be followed.) In place of the nodules which had destroyed the connective tissue, elastic tissue, and vessels, new connective tissue appears with the formation of new epidermis, under which there is an absence of papillæ and elastic tissue (see Fig. 3).

At different sittings the operator may either always use the same method (e g., always *Finsen light*, hot-air treatment, &c., or always freezing and hydrochloric acid), or a combination of methods, which I consider the best—namely, commencing with ethyl chloride and hydrochloric acid and then using the Finsen light after the surface has healed. This combination I consider very effective. For after-treatment with hydrochloric acid the nodules which remain become fairly accessible to photo-therapy. Of course, the hydrochloric acid treatment must not be so energetic as to produce a keloid. One of the properties ascribed to the effect of light is that it has a selective action in lupus and that it produces deep effects either by an imbibition of serum, an emigration of leucocytes, a direct destruction of tuberculous tissue, or, as is very improbable from bacteriological experiments, a direct destruction of the tubercle bacilli themselves. The treatment by freezing and hydrochloric acid, as recommended by me, has the property both of a selective and a deep action. If an area of skin affected with lupus is frozen and then energetically rubbed with hydrochloric acid the stratum corneum, where the superficial nodules are, is the first portion acted on (Fig. 2, *a* and *b*).

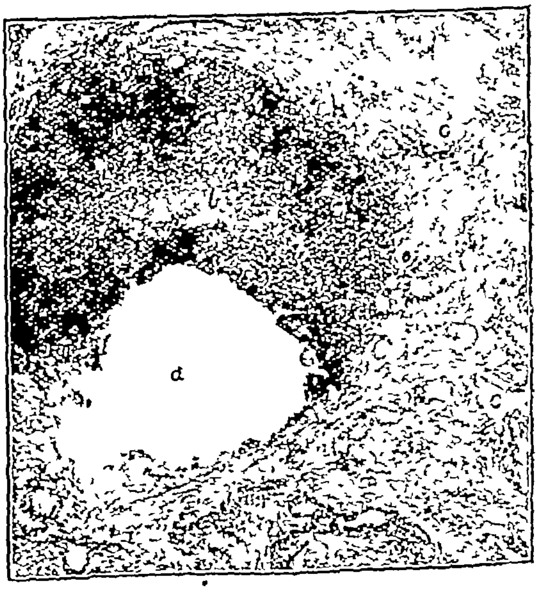
FIG. 2.



Microphotograph. *a* and *b* are two superficial nodules lying just under the epidermis. The epidermis was cauterised especially over these nodules. The piece of skin was excised immediately after a short application of the caustic. Nodule *a* is very dark, nodule *b* dark at places. If the acid had been more thoroughly rubbed in *b* would have been *completely dark too* The deep *seated nodule* (*c*) is still quite lightly stained, as the acid has not reached it. (*d*) Blood vessels. (*e*) Epidermis.

During the application of the caustic it will be recognised that the spots under which nodules are suddenly become visible as dark brown points. On these spots the stratum corneum is always the first to be cauterised (Fig. 2, *a* and *b*). Therefore during the cauterisation more nodules are sometimes seen when the superficial loose epidermic scales have been rubbed away than were originally expected. The healthy skin in the neighbourhood of the nodules remains at first intact and only later becomes cauterised or by stronger treatment destroyed. Apart from this elective effect the hydrochloric acid also exercises a certain deep effect, as may be shown by a staining experiment. If a patch of lupus is rubbed with hydrochloric acid the natural result is that wherever there is a gap in the epidermis (Fig. 2, *a* and *b*) the acid penetrates into the cutis. Now, as already mentioned, this gap in the epidermis first occurs where the tissue is less resistant, therefore where lupus tissue lies, and therefore this area becomes penetrated by the acid to a certain depth and destroyed. The depth to which the acid has penetrated may be accurately ascertained by stains treating an excised portion with a strong basic stain such as polychrome methylene-blue solution. It is clear that in the acid-impregnated cells a marked microchemical reaction occurs between the acid tissue and the basic stain. Microscopically, this is shown by the dark blue colouration of the cells into which the acid has penetrated. In Fig. 2 the nodule *a* is completely penetrated by hydrochloric acid, nodule *b* only in its upper part, and nodule *c* is not penetrated at all. The cells stained dark blue, which have been penetrated by the hydrochloric acid, are in a fair way to disappear and will be later replaced by connective tissue, while the cells stained light blue still require treatment. With regard to the histological changes produced after the application of hydrochloric acid, the nodules and surrounding tissues become saturated with serum and the vessels become enormously dilated. (Fig. 3.) In the piece of skin excised three nodules, of about the same size as in Fig. 2, were rendered visible by the diascope before treatment. These were frozen and thoroughly cauterised. Four weeks afterwards the scab fell off and new epidermis took its place. In a piece of skin excised 12 weeks after the cauterisation there were no histological remains of the nodules which were present before. The limit of the cauterisation may be recognised (1) by the absence of papillæ between *a* and *b*; and (2) by the absence of elastic fibres between *a* and *b*; while in the uncauterised surroundings they are still present.

FIG. 3.



Puncture-cauterisation Point of puncture is *a*. The nodule *b* is dark—i.e, saturated with the hydrochloric acid The vessels *c* are greatly dilated. The connective tissue is infiltrated with serum

The above histological details, notes, and illustrations show that good results can be obtained in lupus by simple and inexpensive means. This is not only the case in recent cases of lupus but also in such as have existed for many years. With regard to the lasting effect of the treatment no exact opinion can as yet be formed, although I have had four cases under observation for two years without any recurrence. But even if there were an occasional recurrence it could be thoroughly and inexpensively treated in the incipient stage. Juliusberg, Rohden, and others have also reported the same good results as I have described. Julius-bèrg has employed the treatment by freezing and hydrochloric acid in Neisser's clinic and for the freezing has used carbonic acid gas. I only approve of this method when many cases have to be treated, because then the cost is reduced. Carbonic acid produces an effect extending to a considerable depth and with a general anæsthetic it can be the effect of freezing used ove stribution of money. His power of his own motion was limited to e mere collection of money. He (the Attorney-General) was strongly opinion that it was of importance that the name of the Royal mily should be connected with the appeal to the public for funds.

Mr. G. Greenwood welcomed the concessions that were being introduced into the Bill.

Sir William Collins expressed satisfaction at the modifications iving the President and the General Council the direction, control, nd management of the Fund, and at the changes that had been introduced in regard to the power of nomination of any future president nd to the summary removal of members of the council. He saw great ifficulty in the way of securing representation of the various London ospitals upon the body which would distribute this money annually.

Mr. Morton urged that it was desirable to have a public audit of the ccounts of the Fund.

Sir Henry Campbell-Bannerman said that honourable Members ust not forget that this Fund was really created by the first President, the present King. The money could not have been obtained but or his influence, and therefore he and those associated with him were ot in the least unreasonable in desiring to have at least something to ay in the expenditure of money. He was glad to say that the Fund ad been a conspicuous success. It had done a great deal of good in he improvements of matters and also in promoting economy. Its xpenses had been at the rate of 1·35 per cent., which he thought was model for hospitals throughout the country. Hitherto, the members f the council had been selected so as to include a large number of ublic interests. Many members of the House might not be aware hat the following were members of the council: the Lords Lieutenant of London and Middlesex, the Bishops of London and Southwark, the Roman Catholic Archbishop of Westminster, the President f the National Council of Evangelical Free Churches, the Chief Rabbi, the Lord Mayor of London, the Chairman of the London County Council, the Governor of the Bank of England, the President of the Royal College of Physicians, and the President of the Royal College of Surgeons. These gentlemen had no doubt rendered good service and they were an ample proof of the desire of the President and his august predecessor to take advantage on the council of persons so well qualified to give advice as these were. There was no reason whatever to doubt that the same practice would continue in the future. It was urged that those names ought to be inserted in the Bill. If that were done it would be difficult to recognise any new body which might come into existence. A further step had been announced that day. The whole of the financial control of the Fund was left practically, as the Bill stood, in the hands of the President; but that was now put an end to and the council had an equal voice with the President in all that concerned the finance of the Fund. As to the suggestion for a public audit, the council was satisfied with the audit at present, but to satisfy the not unreasonable feeling which Mr. Morton had expressed an amendment would be moved to the following effect:—"The accounts of the Fund shall be annually audited by an auditor nominated by the President of the Local Government Board, the remuneration of such auditor to be fixed by the President of the Local Government Board and paid out of the Fund." He thought the concessions which had been made to meet very reasonable criticisms were of extreme importance and deserved to conciliate and attract the support of those who had regarded some of the provisions of the Bill with some suspicion. He hoped that the result of the discussion would be to add to the popularity and success of the Fund and to increase the confidence of the public in its management.

Mr. Balfour expressed the hope that the speech of the Prime Minister and the two amendments which had been announced might enable the House to give a unanimous vote. He would appeal to the House not to interfere with a Constitution which had proved so invaluable in obtaining the confidence of many subscribers in the past. He hoped the House might come to a unanimous decision and proceed to the consideration of the detailed measure on report, without going through the form of a division, which he was sure would be ungracious and inexpedient.

Dr. Rutherford then withdrew his amendment and the Bill was considered. Amendments were introduced into the Bill to give effect to the concessions which members of the Government had adumbrated. This concluded the report stage and the Bill was ordered for third reading.

THE PUBLIC HEALTH BILL.

The Public Health Bill, which was introduced into the House of Commons by Mr. J. W. Wilson, came before one of the Standing Committees of the House on Monday, July 1st. Sir William Holland was in the chair. The object of this Bill is to enable urban authorities to adopt many of the clauses which having been introduced into private Bills of recent years, have been accepted by Parliament, and, further, to confer upon the Local Government Board the power to extend the measure to rural districts. The clauses selected for embodiment in the Bill relate to streets, buildings, and sewers, sanitary provisions, infectious diseases, milk-supply, common lodging-houses, recreation grounds, fire brigades, slaughter-houses, &c.

Mr. J. W. Wilson, in moving a formal amendment at the commencement of the proceedings, said that for 17 years the local authorities had been dependent upon private Bill legislation for any increase in their powers with regard to sanitary arrangements. He further thought that the House of Commons, having allowed this Bill to go through its second reading by consent, recognised its urgent need, not only in the interests of health and sanitation, but for the purpose of saving local authorities an enormous expense. He had received 105 letters from urban authorities heartily approving of this Bill. He recognised the friendly attitude of the President of the Local Government Board towards the Bill. He had acceded to the suggestions of the right honourable gentleman in the hope that he would promise public legislation of a more advanced and comprehensive form than that embraced in the Bill before the Committee.

Mr. Burns said that the unanimity with which the House of Commons had received the Bill had induced the Government to give it its blessing. The Government considered that pending a consolidation of the whole of the Public Health Acts—the responsibility for which he hoped he would be able to bear in his present office—it was advisable even this year to pass a Bill of this kind. They had behind this Bill not only the support of the Members who were backing it, but also the unanimous consent of the House of Commons and the approval of the Chairman of Committees and other authorities of the House of Lords.

Most of the 142 clauses in the Bill were passed without comment, but on a few of them there was some debate. For example, there was some discussion on the clause dealing with children attending school, and a provision was agreed to to the effect that any parent or guardian who sent a child to a school if it had been suffering from an infectious disease, or had been exposed to infection, without receiving a permit from a medical officer should be liable to a fine not exceeding 40s. for each offence.

Clause 82 of the Bill sets forth that the medical officer might enter any public elementary school within the district of a local authority at all reasonable times and examine the scholars. He would further have the power to exclude from attendance any scholar who, in his opinion, was suffering from any infectious disease or was likely to spread infection.

Mr. Cooper raised objections to this power being given, as it might be exercised unreasonably. He was opposed to the child of the poor man being subjected to this inquisitorial action, while the child of the rich man would escape.

An Honourable Member: Will the medical officer be able to take action in the case of a child who has not been vaccinated?

Mr. J. W. Wilson: No. This refers only to infectious disease.

Several members of the Committee were afraid of giving this power to the medical officer even with the consent of the local authority. Eventually the following amendment was accepted in place of the clause:—

"The local authority may authorise a medical officer to enter any public elementary school within the district of the local authority at all reasonable times and to examine the scholars attending the same. He may exclude from attendance therein any scholar who in his opinion is suffering from an infectious disease."

Mr. Burns moved to leave out the clauses dealing with the sale of milk, ice-cream, and the failure to notify diseased cows. He said that the Local Government Board had a Bill before the House dealing with ice-cream, milk, &c.

Mr. Cooper failed to see why the matter should not be dealt with in the Bill before the Committee, as the Bill of Mr. Burns might not succeed in passing through the House of Commons. The need of safeguarding the community from the dangers of ice-cream was not confined to the poor alone. He had ascertained that the dirtiest, filthiest, and most contaminated ice-cream had been sold in the West End of London.

On the promise of Mr. Burns that the whole question would be dealt with in his Bill it was agreed to omit the clauses.

The Bill having passed through Committee was ordered to be reported to the House.

disappearing and quite clear mentally. There is an interval of about ten days in her memory, coinciding with the time when she was at her worst, of which she remembers nothing. She tells us now that she has never previously had any mental trouble. There were no unconsciousness at any time during the illness and no incontinence.

This case is one of peculiar interest both as showing some of the rarer cerebral symptoms of plumbism and as illustrating the great importance of a routine examination of the gums in all cases, obscure or otherwise, as it was not until this blue line was detected that any suspicion of the real cause of the miscarriage, the continued illness, and the cerebral symptoms arose.

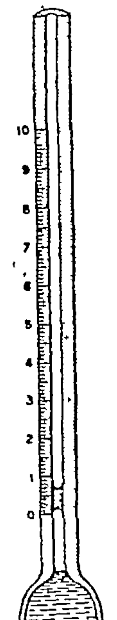
For kind permission to publish this case I am indebted to Dr. Percy Kidd, under whose care the patient was.

A NEW METHOD FOR USING X RAYS.

By A. HOWARD PIRIE, M.D., Ch.B., B.Sc. Edin.,
PHYSICIAN IN THE ELECTRICAL DEPARTMENT AT THE PRINCE OF WALES GENERAL HOSPITAL, TOTTENHAM; LECTURER ON ELECTRO-THERAPEUTICS AT THE NORTH-EAST LONDON POST-GRADUATE COLLEGE.

When it is desired to give a standard dose of x rays the following method is used in this country. A Sabouraud's pastille is placed seven and a half centimetres from the source of the x rays and the part to receive the dose is placed seven and a half centimetres from the pastille. The exposure is then made and when the pastille has changed colour to a standard tint the patient has received a standard dose of x rays. The patient is thus placed 15 centimetres from the source of the x rays. It has been shown that the intensity of x rays varies inversely as the square of the distance. So that if we could place the patient at seven and a half centimetres instead of at 15, the time required for a standard dose would, at seven and a half centimetres, be a quarter of the time required at 15 centimetres. The following method is how I have accomplished this.

I made an instrument as follows. I took a one cubic centimetre pipette about a foot long divided into 100 divisions. I melted one end of the pipette and blew a bulb on it of about the size of a pigeon's egg. Two platinum wires were let through the glass of the bulb and sealed into the glass, so that their free ends projected into the interior of the bulb without touching each other. The bulb was then filled with tap water (see illustration). A drop of water is placed in the lumen of the tube opposite the divisions. This drop adheres to the walls by capillary attraction. I shall call this the indicator drop. The instrument is now ready for use. It is placed in series with the x ray tube and the current which flows through the x ray tube flows through the water in the bulb between the platinum wires. This flow of current decomposes the water in the bulb and bubbles of gas are seen to rise from the platinum wire. These bubbles collect in the lumen of the tube and so force the indicator drop to rise. When a child's scalp is placed at 15 centimetres from the source of the x rays while this instrument is in series with the x ray tube, and the indicator drop has risen 11½ divisions, then the scalp has received a standard dose of x rays and epilation will follow. If at the same time a Sabouraud's pastille was used as a control it will be found to have reached the standard tint.



c to coil; x to x ray tube. The drawing is in ½-metre scale.

Now comes the chief use of this instrument. Suppose the above exposure took 12 minutes at 15 centimetres, then at seven and a half centimetres it would have required only three minutes. It is not possible to use Sabouraud's pastilles for epilating at seven and a half centimetres as they are not sufficiently sensitive. By means of my instrument this is possible, and I have found that by placing the scalp at seven and a half centimetres from the source of the x rays and collecting three divisions of gas in the instrument epilation follows.

Results.—I have worked with four different installations and have got the same results with all. I usually require from two to three minutes to produce epilation on a patch of ringworm in a child. For this purpose I place the scalp in contact with the x ray tube (having grounded the positive wire for safety). The head is thus seven centimetres from the bull's-eye of the target—i.e., the point on the anticathode from which the x rays originate.

I have worked at various distances of from seven to 15 centimetres between bull's-eye and scalp for producing epilation and have worked out the following

Table of Equivalents.

Distance in centimetres between the bull's-eye of the target and the scalp for epilation	7	8	9	10	11	12	13	14	15
Number of divisions the indicator drop must rise in order to produce epilation	2½	3¼	4¼	5¾	6¼		8½	10	11½

I have produced epilation in three minutes and in 20 minutes, trusting simply to this meter. When treating the whole scalp for ringworm it does not offer any advantage over Sabouraud's method, but for other purposes, such as a single patch of ringworm, it requires only a quarter of the time that Sabouraud's method does. This meter might be called a quantimeter, as it measures the total quantity of electricity passing through an x ray tube. This quantity is continually varying, as a glance at a milliampèremeter will show. For this reason a milliampèremeter cannot be used for estimating the quantity of x rays given out. My quantimeter does not measure the quantity of electricity passing at any given moment, but measures the total quantity that has passed in a given time, and this is a measure of the quantity of x rays given out in that time.

I have described the instrument in its simplest form. There are some simple improvements added to it for practical use. For instance, when the indicator drop has reached the top of the tube it automatically returns to a prearranged spot in the tube and is ready to start again on its upward journey. It can also be arranged that when the drop has mounted ten (or any number of) divisions it makes a contact which automatically cuts off the current and the exposure comes to an end. Messrs. Watson and Sons of Holborn, London, have made a quantimeter for me.

I shall sum up the advantages and disadvantages of the quantimeter. Its *disadvantages* are as follows:—

1. *Heat.*—If the bulb containing the water is fairly large and the platinum wires are kept near each other the rise of temperature is negligible. In this connexion I have calculated out the following: 4·8 divisions of the quantimeter at 50° F. becomes 4 9 divisions at 60° and become five divisions at 70°.

2. *Barometric pressure* has some influence, but with small quantities of gas it may be neglected.

3. *Valve tube.*—It is absolutely essential to use a valve tube or adjustable spark gap as the quantimeter will measure the reverse current through the tube unless this is suppressed. Care must be taken not to measure a current that is not producing x rays such as the current used to soften a tube.

4. All x ray tubes do not give out the same quantity of x rays for the same quantity of current supplied. But how has the current been measured? Usually by the milliampèremeter which varies continually and does not measure the total current but only the current for the moment. I have found practically that any tube having a spark gap of from two to six inches responds correctly to this quantimeter.

Advantages.—The x ray worker can with the aid of this meter accomplish in an hour what formerly took four hours. This is its only advantage and its main object.

It may be used as a milliampèremeter to measure the mean current that has flowed during a certain time; thus, a constant current of 0 9 milliampère flowing for five minutes will liberate 0·05 cubic centimetre of gas; therefore, if five divisions of gas have been collected in the quantimeter in five minutes the mean current for that time must have been 0·9 milliampère. This measurement is for 70° F.

An interesting deduction is made from this quantimeter by collecting the oxygen and hydrogen separately. By so doing it is possible to calculate the percentage of reverse current passing through the x ray tube. If reverse current is passing a [illegible] will collect in the unning, Charles John Hope, M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Victoria Hospital for Children, Tite-street, Chelsea, S.W.

ogan, Frederick Thomas Bishop, L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer for the Bishopsworth District of the Long Ashton (Somerset) Union.

acphail, Alexander, M.B., M.S. Glasg., has been appointed Lecturer on Anatomy at the Charing Cross Hospital Medical School.

obbs, C. H. D., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Grantham District of the county of Lincoln.

Rynne, M. A., M.D. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Cheltenham District of the county of Gloucester.

St. Johnston, Thomas Reginald, M.R.C.S., L.R.C.P. Lond., M.S.A., has been appointed Government Medical Officer in Fiji.

ymes, J. Odery, M.D. Lond., has been appointed Physician to the Bristol General Hospital.

Williamson, Herbert, M.B., M.R.C.P. Lond., has been appointed Assistant Physician-Accoucheur to St. Bartholomew's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Abergavenny, Monmouthshire Asylum.—Senior Assistant Medical Officer. Salary £250 per annum, with board, apartments, washing, and attendance.

Ayr County Hospital.—Resident House Surgeon. Salary £70 per annum, with board and residence.

Ayr District Asylum.—Junior Assistant Physician, unmarried. Salary £120 with board, apartments, and laundry.

Birmingham Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £104 per annum, with apartments, rations, and attendance.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance.

Bristol Royal Infirmary.—Casualty House Surgeon for six weeks.

Burnley, Victoria Hospital.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing.

Bury St. Edmunds, West Suffolk General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Cancer Hospital, Fulham-road, S.W.—Medical Officer in Charge of the Electrical Department. Salary £26 5s. per annum.

Chelsea Infirmary, Cale-street, S.W.—Second Assistant Medical Officer. Salary £90, rising to £100, with board, apartments, coals, gas, and washing.

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months, subject to re-appointment. Salary £60 per annum, with rooms, board, washing, and attendance.

Derby, Derbyshire Royal Infirmary.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

Essex and Colchester General Hospital.—House Physician. Salary £80 per annum, with board, residence, and washing.

Egypt.—Sub-Inspector of Ophthalmic Hospitals, unmarried. Salary £500 a year.

Gloucester General Infirmary and Gloucestershire Eye Institution.—Assistant House Surgeoncy for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £100, with board, residence, and laundry.

Hastings, St. Leonards, and East Sussex Hospital.—Physician.

Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Maida Vale, W.—Physician for the Diseases of Women.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging.

Liverpool Stanley Hospital.—Assistant Honorary Ophthalmic Surgeon.

London Temperance Hospital.—Assistant House Surgeon, non-resident, for six months. Salary at rate of £75 per annum.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with rooms, attendance, board, and washing.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

Manchester Royal Infirmary.—Surgical Registrar. Salary £80 per annum.

Middlesex Hospital, W.—Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence.

Newport and Monmouthshire Hospital.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.

Northampton General Hospital.—House Surgeon, unmarried. Salary £80 a year, increasing to £100, with apartments, board, washing, and attendance.

Norwich, Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

Nottingham Children's Hospital.—House Surgeon (female) for six months. Salary at rate of £80 per annum, with board, residence, and washing.

Oxford, Radcliffe Infirmary and County Hospital.—Honorary Assistant Surgeon.

Poplar Hospital for Accidents.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

Rotherham Hospital and Dispensary.—Senior House Surgeon, Salary £110 per annum, with rooms, commons, and washing. Also Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

Royal Eye Hospital, St. George's-circus, S.E.—Refraction Assistant. Salary £40 per annum. Also Clinical Assistants.

Royal Institute of Public Health.—Demonstrator of Comparative Pathology and Bacteriology.

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

St. Luke's Hospital, Old-street, London.—Clinical Assistant, unmarried, for six months, board, apartments, and washing provided.

Seamen's Hospital Society.—Assistant Physician. Also assistant Surgeon.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.

Stockport Infirmary.—Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

Stockton-on-Tees, Stockton and Thornaby Hospital.—House Surgeon. Salary £180 per annum, with residence, board, and washing.

Taunton, Taunton and Somerset Hospital.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Teignmouth Hospital, South Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

West Bromwich District Hospital.—Senior House Surgeon, unmarried. Salary £110 per annum, with, board residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and laundry.

Winchester, Royal Hampshire County Hospital.—Honorary Physician-in-Ordinary.

Births, Marriages, and Deaths.

BIRTHS.

Brown.—On June 30th, at Carlton House, Gloucester, the wife of Walter Brown, M.B., of a daughter.

Dickie.—On June 29th, at Ryedale-terrace, Middlesbrough, the wife of W. S. Dickie, F.R.C.S., of a daughter.

Edge.—On the 1st inst., at Granville House, Tettenhall-road, Wolverhampton, the wife of Frederick Edge, M.D., F.R.C.S., M.R.C.P., of a son.

Howden.—On June 30th, at Cambridge-terrace, Dover, the wife of Ian Howden, M.D., J.P., of a son.

MARRIAGES.

Birt—Kidd.—On June 29th, at St. Michael's, Blackheath, S.E., A. Cyril Birt, M.R.C.S., L.R.C.P., D.P.H., to Gertrude Isabelle Kidd, daughter of Joseph Kidd, M.D.

Dickins—Taunton.—On June 26th, at St. Nicholas, Worcester, Sidney John Oldacres Dickins, M.D., to Cicely Margaret, elder daughter of William Whitchurch Taunton, B.Sc., M.R.C.P.

MacWatters—Richards.—On May 1st, at St. John's Church, Peshawar, by the Rev. H. W. F. Fagan, chaplain, R. C. MacWatters, M.B., I.M.S., to Nona, youngest daughter of the late Dr. Geo. Richards of Ross-on-Wye.

Trist—Owen.—On June 26th, at St. Luke's Parish Church, Chelsea, by the Venerable the Archdeacon of Middlesex, assisted by the Rev. W. B. Trevelyan, vicar of St. Matthew's, Westminster, and the Rev. Owen Slacke, curate-in-charge *Coles Hill*, Bucks (cousin of the bride), John Ronald Rigden Trist, M.R.C.S., L.R.C.P., Crest House, Putney, elder son of Herbert H. Trist *of* 22, Vernon-terrace, Brighton, to Louisa Harriet, eldest daughter *of* E. Annesley Owen, Esq., Barrister-at-Law, of 94, Oakley-street, Chelsea, and of the Inner Temple.

DEATHS.

Benson.—On June 22nd, 1907, at Chatham, New Brunswick, Canada, John Stafford Benson, M.R.C.S.E., aged 69 years, son of the late Stafford Benson, M.R.C.S.E., formerly of Appledore, Devonshire, England.

Fleury.—On June 23th, at Lower Baggot-street, Dublin, Charles Robert Fleury, M.D., in his 72nd year.

Gairdner.—At Bracondale, Colinton, Midlothian, on Friday, June 28th, very suddenly, Sir William Tennant Gairdner, K.C.B., LL.D., M.D., aged 82.

Thorp.—On July 2nd, at Elgin-crescent, Bayswater, Sidney Thorp, M.R.C.S., aged 63.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Complications and sequelæ were uncommon; albuminuria was rare; paralytic symptoms were noted in four cases; in no case was there nasal or laryngeal implication, or was tracheotomy necessary. Two children (both girls aged nine years) died from cardiac dilatation and failure; of these, one was the first case of the series and antitoxin treatment was delayed. Several of the children subsequently developed ulcerations of the tonsils; these occurred late, during convalescence, and gave rise to some anxiety, but they were found not to be associated with the presence of bacilli, and they yielded rapidly on being carefully painted with liquor iodi. The bacillus remained persistently in many of the throats, more especially in those in which enlarged tonsils or adenoid growths were present. I have remarked that the same effect of these conditions was noticed in children who did not develop diphtheria.

Especial interest attaches to the use made of antitoxin. No other instance is known to me in which it has been sought to immunise by its use so large a number of children. The serum used was that supplied by a well-known firm in phials containing each 2000 Ehrlich-Behring units and was not highly concentrated. In most of the prophylactic doses the bulk of fluid was sufficiently small to allow of its being given by means of an ordinary hypodermic syringe; the injections were made under the prepared skin of the back below the angle of the scapula, a fresh needle from a supply kept in spirit being used in each case.

Of definite ill-effects following upon the treatment there were none. One girl showed a general urticarial eruption lasting 36 hours after the first injection, but none after the second. One boy had a spreading erythematous blush around the puncture, arising within a few hours of the second injection; this was accompanied by a slight rise of temperature and passed off in two days. The children generally regarded the treatment as a not unpleasant mild form of excitement. It was thought that a slight depression followed and that their play was for a few hours afterwards less noisy. No other effects whatever were noted. There was, of course, no evidence that the treatment had any effect in hastening the elimination of bacilli from the children's throats; much trouble, in fact, was caused by their tenacity.

It has been shown that attempts were made simultaneously to rid the school of infection by isolating all children with infected throats and to render all the children immune by the administration of antitoxin. Had it been supposed that it was feasible by one examination of a swabbing from every child's throat to differentiate the infected antitoxin might not have been used. It is well known, however, that more than one such examination is necessary before freedom from infection can fairly be assumed and multiple examinations before discharge now form part of the accepted routine in most fever hospitals. There was ample evidence that infection was rife amongst the children in Percy House Schools after Feb. 13th; eight cases of diphtheria actually arose in spite of the protection which was afforded by the treatment adopted and bacteriological proof was abundant that many infected throats were present amongst children other than those who had been isolated. There can, I consider, be no doubt that the arrest of the spread of the epidemic was due to the prophylactic action of antitoxin. Its administration upon so large a scale was not undertaken without serious consideration and it is satisfactory to be able to record that its use appears to have been amply justified by the results attained.

Isleworth.

ON THE USE OF A NEW FLUID FOR THE HÆMATOCYTOMETER.

BY ALEXANDER EDINGTON, M.D. EDIN., D.P.H. EDIN. AND GLASG., F.R.S. EDIN.,
LATE DIRECTOR OF THE GOVERNMENT BACTERIOLOGICAL INSTITUTE, CAPE COLONY.

WHILE the enumeration of the red and white blood corpuscles as an aid to diagnosis of obscure conditions has been more or less in vogue for more than a quarter of a century, its utility, not only as a diagnostic aid but as indicating alterations under treatment, has only attained the present general acceptance within recent years. But even now the practice of making blood counts is by no means universal. An explanation for this may possibly be found in a want of appreciation of the method by some, want of time in the case of others, or in the undeniable fact that some little dexterity and patience are requisite for obtaining trustworthy results. The last reason is perhaps the most salient and one must admit that the use of even so good an instrument as the Thoma Zeiss hæmatocytometer requires dexterity and precision, while accuracy is to some extent impeded by the want of a suitable diluting fluid.

Of all the fluids in use—and there are a considerable number—the best that can be said of them is that they make an approach to being isotonic with normal blood. "A solution containing just such a percentage of salt as suffices to keep the corpuscles unaltered in form and without removal of any of their hæmoglobin is 'isotonic.' For human blood a solution of common salt is isotonic with 0·9, for defibrinated ox blood with 0·6, and about the same for frogs' blood. Very slight differences of external condition will tend to alter the permeability of the blood corpuscles both for hæmoglobin and for other substances" (Schäfer's "Textbook of Physiology").

The normal specific gravity of the blood in a healthy subject is from 1058 to 1062 but in departures from the normal the specific gravity may be much lower and has been found even so low as 1033. With a lower gravity the hæmoglobin falls in an almost constant fashion, so that while with a specific gravity of 1057–60 there may be 85 per cent. to 95 per cent. of hæmoglobin, with a specific gravity of 1033–35 the hæmoglobin will have fallen to 25 per cent. to 30 per cent. When coagulation is prevented the corpuscles of drawn blood very soon sink, leaving the yellow plasma as a supernatant fluid, and it is evident that if hæmoglobin is given up by the corpuscles to the plasma it is very soon eliminated from that fluid, most probably by the kidneys. In various kinds of experimental hæmolyses I have found free hæmoglobin in the plasma antecedent to its appearance in the urine. It is probable, therefore, that changes in the amount of hæmoglobin are in great part due to abnormal permeability of the corpuscles and also to their destruction. In any case, supposing the blood to be examined to be that of an abnormal individual, we may assume that the specific gravity is almost certainly below the normal. If this be the case then the use of a fluid which is isotonic for healthy blood is most certainly improperly constituted for a blood of lower specific gravity. It seemed to me, therefore, of some importance to determine whether one could not prepare a fluid which, without having great regard to the isotonic quality, would be useful for any kind of blood.

Some ten years ago I first used neutral citrate of potassium as a means to maintain large quantities of pathological bloods in a fluid condition so that they could be used for inoculation, and the plan I then adopted has, since that date, found its way into most bacteriological institutions What, however, struck me as remarkable was the fact that the red blood corpuscles maintained their shapes and characters in a marvellous manner, so that even blood films could be made with blood so prepared. I have therefore prepared the following solution for use with the hæmatocytometer: neutral citrate of sodium, 7·5 grammes; formalin (40 per cent.), 2·0 cubic centimetres; dahlia (Grübler's), 0·03 grammes; chloroform 5 drops; and distilled water, 250 cubic centimetres. In preparing the solution it is better to mix the stain with the water, rubbing down the former with a few drops of the latter first, then to add the citrate and formalin. The solution should be left for a day or two without filtering so as to deposit all the less soluble portions of the dye. The solution is easily made and keeps well when kept in a dark and cool place. If, however, it has not been used for some time it is advisable to filter off a small portion for immediate use. In less than a minute after the diluted blood has been placed on the slide one will find the red corpuscles deposited on the glass so completely that nearly all are in focus, while the refractive index of the corpuscles is so well maintained that they are very easily counted.

In practice I prefer to eject one or two drops from the tube of the hæmatocytometer and thereafter to empty the remainder into a small glass tube which is closed by a well-fitting stopper. By this means the mixed blood and fluid may be sent long distances for examination. Messrs. Thomson, Skinner, and Hamilton, of 38, Sauchiehall-street, Glasgow, now supply such tubes at a nominal cost. The hæmatocytometer tube, after using this solution, is very readily cleaned, a circumstance which may commend itself to many. The rubber tube supplied with the Thoma-Zeiss hæmatocytometer is too short. I prefer using a rubber tube

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. J. W. Carr: Clinique. (Medical.) 5.15 P.M.: Lecture:—Dr. G. F. Still: Infantile Diarrhœa.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1907, which was completed with the issue of June 29th, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., *carriage extra.*

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Redditch Indicator, Alcester Chronicle, Hertfordshire Mercury, Westminster Gazette, Westminster and Pimlico News, Tottenham and Edmonton Weekly Herald, West Sussex Gazette, Daily Dispatch (Manchester), Montreal Gazette (Canada), Dublin Daily Express, Huddersfield Weekly Examiner, Canterbury Times, Dublin Evening Telegraph, Dundee Advertiser, Science Siftings, Liverpool Daily Post and Mercury, Oxford Review, Daily News, Bath Herald, Yorkshire Observer, Statesman of India, Wimbledon Gazette, Broad Arrow, &c.*

The crural canal was closed by stitching Poupart's ligament to the fascia covering the pectineus. The wound was then closed in the usual way. The left hernia proved to be of the ordinary inguinal type and a radical cure was done.

Another curious fact about this case was the woman's colour. She was of a bluish hue; this came on gradually about six years ago and she could give no cause for it. The only medicine which she had taken with any regularity had been in the form of some proprietary liver pills, of which she took two or three a week. (The blue man at Barnum and Bailey's circus derived his colour from taking silver pills.) Her blueness is increased when she is unwell and in cold weather it is especially well marked in her extremities. The heart and lungs were found to be quite normal and there was no clubbing of the finger tips or curving of the nails. A blood count was carried out. The red blood corpuscles were 4,496,000 and the leucocytes 3000 per cubic millimetre respectively; and the hæmoglobin 90 per cent. of the normal. A film was also made but nothing abnormal was found. Dr. Alexander Morison who saw the case said that, in his opinion, the condition was vaso-motor in origin and allied to Raynaud's disease. The patient left the hospital four weeks after the operation.

Mr. Stabb has kindly given me his permission to publish this case.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Suppuration in an Ovarian Cyst caused by the Bacillus Typhosus.—Exhibition of Specimens.

A MEETING of this society was held on July 3rd, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. FRANK E. TAYLOR read a short communication on Suppuration in an Ovarian Cyst caused by the Bacillus Typhosus. The patient, a IV-para, aged 37 years, was admitted into the Chelsea Hospital for Women in April, 1907. She had lived in India for the last 15 years and had enjoyed good health until April, 1906, when she had an attack of typhoid fever. During convalescence a freely movable abdominal tumour was discovered. This gradually increased in size but caused no further signs or symptoms. On opening the abdomen the tumour was found to be a cyst of the left ovary deeply congested or inflamed. There were some adhesions to the omentum only. The cyst was easily removed entire. Recovery was ideal. The tumour was a unilocular cyst of the size of a man's head and held two and a half pints of greenish-yellow pus free from odour. A pure culture of bacillus typhosus was obtained from the pus. The organism was very thoroughly investigated and gave characteristic reactions. It agglutinated the serum of an immunised rabbit in dilutions of 1 in 4000. A Widal's test with the patient's serum gave a positive reaction with 1 in 1000 in one hour. Dr. Taylor considered that infection reached the cyst by way of the blood-stream and that this case demonstrated the pyogenetic properties of the typhoid bacillus. Bacteriologically he classed post-typhoid suppuration under three headings—viz.: (1) a mixed infection, where both pyogenetic cocci and the typhoid bacilli were present; (2) a secondary infection, caused by invasion of pyogenetic cocci into an organ whose resisting power had been lessened as the result of the typhoid fever, and (3) a pure infection, caused by the bacillus typhosus alone, which undoubtedly possessed pyogenetic properties under suitable conditions.—The PRESIDENT asked Dr. Taylor whether Widal's reaction was considered positive proof of the presence of typhoid fever. He knew that physicians did not regard it as such a few years ago. He was surprised to hear that the bacillus typhosus could survive in ovarian fluid for 12 months.—Mr. ALBAN H. G. DORAN referred to his case of perforating ulcers of the ileum from obstruction after ovariotomy, published in the thirtieth volume of the "Transactions of the Pathological Society."—Dr. TAYLOR, in reply, said that the value of Widal's reaction in diagnosis greatly depended upon the technique of its performance, especially with regard to the dilution and time limit employed. The reaction was not absolutely infallible.

The following specimens were shown:—

Dr. TAYLOR: Two Uteri showing a Fundal Ligament after Hysteropexy.

Mr. J. H. TARGETT: Hæmorrhage into the Substance of a Uterine Fibroid.

Miss L. B. ALDRICH-BLAKE: (1) Skeleton of an Extra-uterine Fœtus from a Woman in whom there was no history suggestive of such a Gestation; and (2) Carcinoma of the Cervix in a Uterus, one Horn of which was Undeveloped.

Dr. LEWERS: Two Specimens of Fibroid associated with Bleeding after the Menopause.

The PRESIDENT: A Calcified Fibroid Enucleated for Bleeding 15 years after Oöphorectomy.

Dr. C. J. N. LONGRIDGE: (1) A Baby's Breast; and (2) Diaphragmatic Hernia.

Mrs. M. A. D SCHARLIEB: A Myxomatous Fibroid weighing 23½ pounds removed by Abdominal Hysterectomy.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Making of a Shelf below the Unduly Mobile Kidney.—Treatment of General Paralysis and Tabes Dorsalis by Vaccines and Anti sera.—Bacillus in the Blood of Persons suffering from General Paralysis.

A MEETING of this society was held on July 3rd, Dr. J. O. AFFLECK, the President, being in the chair.

The following specimens were shown:—Dr. W. FORD ROBERTSON and Dr. G. DOUGLAS MCRAE: (1) Rats showing Paresis resulting from action of bacillus paralyticans brevis; and (2) Microscopical Preparations from cases of General Paralysis, illustrating bacillary infection.

Dr. DAWSON F. D TURNER showed two patients: (1) a case of Rodent Ulcer on the Nose, which had been treated by him with the x rays for three months without effect, but which yielded readily to the radiations of ten milligrammes of radium; and (2) a case of Rodent Ulcer in the Nose of a man, aged 61 years. When first seen the ulcer measured three-quarters of an inch across and had hard raised margins. One application of zinc electrolysis, 30 milliampères for ten minutes caused the floor to heal over and a great part of the hard margin to melt away. A second application had since been made and the case had greatly improved. Photographs of the patients before and after treatment were shown.

Dr. A. LOGAN TURNER showed a patient successfully treated by x rays for Lupus of the Larynx. The rays were applied through the skin over the cartilages of the larynx; treatment was carried on during 12 months and the condition was cured. The case occurred in a girl aged 12 years.

Mr. J. W. STRUTHERS showed a boy suffering from Trigeminal Nævus with Epilepsy and Paresis of the Arm and Leg on the side opposite to the nævus. This association of nævus with epilepsy had been observed previously and in certain cases there was a nævoid condition of the dura mater on the side corresponding to the nævus and operation had improved the condition. The dura mater was sensitised by the fifth nerve. The dura mater was exposed in this case but was found to be normal.

Dr. NORMAN WALKER exhibited:—1. A woman suffering from Mixed Infection of Lupus Vulgaris and Specific Disease. The lupus commenced when she was four years of age and spread upwards from the legs. At the age of 19 years it affected the face and mouth. The patient's father died from pulmonary tuberculosis. Finsen light and x rays had been tried on the patient without benefiting her condition. She was admitted to the Royal Infirmary in February of this year. Oleate of mercury was applied to the lupus of the face and neck and at first 15 grains of iodide of potassium were given three times daily and then 30 grains. After the larger doses were commenced the condition improved most markedly. She had also had three injections of tuberculin ($\frac{1}{1000}$th milligramme); the negative and positive phases with a rise in the opsonic index were noted. 2. An Epileptic Girl with a Well-marked Rash due to Bromide of Potassium. 3. A Man suffering from Herpes Iris. 4. Acne Keloid.

Mr. H. ALEXIS THOMSON read a paper on the Making of a Shelf below the Unduly Mobile Kidney. He said that the principle of making a shelf below the unduly mobile kidney as an alternative to fixing the organ by means of stitches was introduced some years ago in America and specially advocated by Harris of Chicago. Regarding the causes of undue renal mobility, it must be confessed that, in spite of

The Croonian Lectures

ON

PLAGUE.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th, 1907,

BY W. J. R. SIMPSON, M.D. ABERD.,
F.R.C.P. LOND.,
PROFESSOR OF HYGIENE AT KING'S COLLEGE, LONDON; GOVERNMENT COMMISSIONER TO INQUIRE INTO CAUSES AND CONTINUANCE OF PLAGUE IN HONG-KONG, 1902, ETC.

LECTURE II.[1]

Delivered on June 20th.

THE PRESENT PANDEMIC.

MR. PRESIDENT AND FELLOWS,—The present pandemic has no connexion with the plagues arising in Mesopotamia the chief features of which, as shown by Tholozan, were, during the latter part of the nineteenth century, those of comparative mildness, spontaneous cessation, and self limitation, irrespectively of preventive measures. It would appear that the strain of the Mesopotamian virus has become attenuated both in powers of attack and powers of diffusion and that it required a virus derived from a new source or from another endemic centre to produce a plague endowed with more virulent and diffusive qualities.

The Chinese endemic centre in Yunnan, from which the present pandemic is derived, is, like the endemic centres in Arabia and India, between 5000 and 7000 feet high, and in this respect differs from some of the older endemic centres which are low lying. Yunnan has been known as an endemic centre of plague since 1870 but there are Chinese records which seem to indicate that the disease probably existed there for over 100 years, for mention is made of a strange and fatal rat disease prevailing at the end of the eighteenth century which also infected the inhabitants. There are no records discovered which make the endemic centre older than this and there is no evidence to show that the Black Death of 1348 arose from Yunnan. It is not known exactly when the present pandemic overflowed its boundaries and invaded the adjoining provinces of Kwangtung and Kwangsi. Plague had passed over the boundary several times during the Mahommedan rebellion in Yunnan and in 1867 reached Pakhoi, a small seaport on the southern coast of China, but there appears to have been no very extensive epidemic. As far as can be ascertained it was about the year 1890 that the disease began to show unusual activity. At that time the annual recrudescences in Mentze, one of the principal trading towns in the south-east portion of the province, became more severe and there was an extension of the disease to some of the towns situated on the West or Canton River and which have trade relations with Mentze and Canton. Gradually an extended area of the western parts of Kwangsi and Kwantung became affected and in January, 1894, Canton was attacked. Canton is the chief port as well as the largest and most important city in Southern China. It is only 80 miles from Hong-Kong, which, situated at the mouth of the Pearl River, contains a population that is mainly Cantonese, and so great is the intercourse between them that Hong Kong has been styled the suburb of Canton. Hong-Kong became infected in May, 1894. Recrudescences of plague have occurred more or less in Canton and Hong-Kong since. Canton and Hong-Kong are the great marts and distributing centres for the produce of Southern China and have trade connexions with the southern parts of China, the neighbouring islands of the Pacific, and with India, Australia, Japan, and America. They were accordingly favourably situated as distributors of plague to all those countries adjacent and distant with which they had commercial relations. Their ships carried infection to the seaports of other countries, and these in their turn infected other places. The course of the spread of plague has differed from all previous pandemics in that its distribution has been by sea routes, in contradistinction to former pandemics which spread by land routes and coasting vessels. With the exception of India and one or two places in South Africa and America the infected localities are mostly on the coast, and the history of their infection is importation of the disease from some infected port with which they carry on commercial relations. Any circumstance which increases to an unusual extent the transport of goods from infected ports increases the risk of importation of the disease. Thus, the war in South Africa, with its enormous shipments of grain and fodder from the Argentine and from India, whose ports were infected with plague, introduced the disease into Cape Town and Port Elizabeth, where the rats in the docks were the first to become infected. The Russo-Japanese war was, fortunately for Europe, out of the zone of any badly plague-infected district.

Many places have been infected in different parts of the world, but none outside India have hitherto given rise to any very serious epidemic. Still, notwithstanding its apparent inability to develop into an epidemic, yet the disease has in many instances when imported into a locality shown a remarkable persistence as displayed by the annual recurrence of sporadic cases at the season of the year favourable to epidemic plague. The potentiality of plague becoming epidemic in such localities is there all the same and no country is safe while it retains infection.

THE EPIDEMIC IN INDIA.

At present, however, the chief interest of this pandemic lies in India. Imported into the city of Bombay in 1896 from Hong-Kong it broke out in epidemic form in September of that year, and by the end of April, 1897, when the first epidemic was over, it had caused 11,000 deaths. Every year there has been a recrudescence and the total number of deaths from plague in Bombay since its appearance till the end of 1906 is 150,000. From Bombay city it spread to the Bombay Presidency, chiefly by coasting boats and by the railways carrying fugitives infected with plague to their native villages. By December, 1897, 50,000 deaths had occurred in the Presidency, and a few deaths in some of the other provinces. It has continued ever since in this Presidency and has, up to the end of April, 1907, caused 1,500,000 deaths. Gradually the disease has spread to the other provinces of India, affecting some severely and some lightly, and the grand total of deaths from plague in India, as shown in the following statement of annual deaths, amounts to over 5,000,000:—

Total Recorded Annual Deaths from Plague in India.

Years.	British Territory.	Native States.	Total.
Sept., 1896, to end of 1897	57,000	—	57,000
1898	89,200	27,000	116,200
1899	102,300	36,600	138,900
1900	73,500	19,200	92,700
1901	234,600	46,100	280,700

			5,321,800

The population of British territory is 232,000,000 and that of the native states 62,000,000. The 5,000,000 deaths represent accordingly one death in every 60 of the inhabitants of India. The mortality during the later years is very much greater than in the earlier, the deaths in the last five years and four months reaching over 4,500,000.

The fact that India is an immense country with nearly 300,000,000 inhabitants has often been considered as minimising the gravity of the situation which 5,000,000 of deaths would otherwise represent, and the argument is employed that in such a large country it is impossible to deal with the disease. 1,000,000 deaths a year in a population of 300,000,000 is viewed only as 1 death in 300 of the inhabitants and from that point appears not to have much influence on the vast population. It is once more the fallacy of averages. There is the old story of the man who, assured that the average depth of a river was four feet, endeavoured to cross it and was drowned. He had not reckoned that it might be shallow in some parts and deep in others. Plague is not epidemic over the whole of India. But, even if it were, and admitting that India, including Burma, is greater by 12,000 square miles than the whole of Europe, excluding

---

[1] Lecture I. was published in THE LANCET of June 29th, 1907, p. 1757. No. [illegible]

Microscopical preparations were exhibited showing very abundant diphtheroid bacilli in the brain of a general paralytic, granular bacilli in a nerve cell in the brain of another case from which a culture of a diphtheroid bacillus had been obtained, and several diphtheroid bacilli in a lymphocyte in the centrifuge deposit from the cerebro-spinal fluid of a general paralytic withdrawn during life.

Dr. GEORGE M. ROBERTSON read a communication on the Presence of a Bacillus (Muirhead's Diphtheroid) in the Blood of Persons suffering from General Paralysis and Observations on the Bacillus Paralyticans. The researches, of which this paper was a summary, were inspired by the Morison lectures, delivered in 1906 by Dr. Ford Robertson, pathologist to the Scottish asylums, in which he stated that "a special diphtheroid bacillus," which he named "the bacillus paralyticans, was the specific etiological factor in the production of general paralysis and tabes dorsalis." The researches were carried out under Dr. Robertson's direction with the coöperation of all the members of the medical staff of the asylum. Dr. Robertson pointed out that Dr. Ford Robertson had not given such distinctive cultural or other tests as would clearly identify the bacillus paralyticans, and indeed had left its exact identity "an open question." The objections to this position of uncertainty were stated but the difficulty of identification was overcome in this research by obtaining a culture of the organism. It was found *not* to be the Klebs-Löffler bacillus. Owing to the fact that diphtheroid organisms are frequently present in the alimentary, respiratory, and other mucous tracts of persons who are not suffering from general paralysis their existence in these regions in general paralysis, as Dr. J. W. H. Eyre and Dr. Flashman pointed out, does not necessarily have any special pathogenic significance. Dr. Ford Robertson obtained most of his diphtheroids from these regions and in order to avoid a possible source of error in this research cultures were made from the blood and cerebro-spinal fluid. It was pointed out that cultures made after death were also open to fallacy owing to the liability to terminal invasions by micro-organisms and to the rapid putrefaction of the bodies of persons dying from general paralysis. Such observations should only be secondary or confirmatory. The *modus operandi* of the method for obtaining cultures from the blood was then described and the measures adopted to obtain sterility of the skin of the patient and the instruments employed. 300 cubic centimetres of broth inoculated with 10 cubic centimetres of blood from four healthy controls proved sterile, as did the blood from 25 insane persons. Ten cubic centimetres of the blood of a general paralytic suffering from a severe congestive seizure were withdrawn. Broth was inoculated and incubated for 48 hours. On naked-eye examination it appeared unchanged and sterile, but on examining a hanging-drop specimen organisms were seen. Plating was done in the ordinary way but every attempt proved unsuccessful. As organisms were seen in hanging-drop specimens, and as organisms were stained in a centrifugalised deposit obtained from the broth, and as organisms were seen in blood-smears, owing to the non-success of plating, it was decided to inoculate mice and guinea-pigs. This was done by Dr. T. Shennan at the laboratory of the Royal College of Physicians. After four days a mouse was killed and cultures were made from the spleen and liver and a diphtheroid organism was successfully recovered from both sources. Owing to the difficulty of plating out special methods were employed and successful plate cultures were made without inoculating mice. Diphtheroids were obtained 15 times from the blood and cerebro-spinal fluid of seven general paralytics. These were tested on seven solid and 13 fluid media and proved to be the same organism, there being variability only in the case of milk litmus. This diphtheroid was not the bacillus paralyticans of Dr. Ford Robertson, and the latter organism was never isolated at any time in these researches. Dr. Ford Robertson had altered his original views and now stated that there were two forms of the bacillus paralyticans, a longus and a brevis. These belonged to different groups of diphtheroids, gave different serum reactions, required different sera in treatment, and produced two distinct varieties of general paralysis. He recently supplied the speaker with cultures of his second or brevis form. It was found that this had once been obtained post mortem in the cerebro spinal fluid associated with a streptothrix in a general paralytic. The streptothrix was, however, obtained in pure culture from the heart blood, and in this case during life the Larbert bacillus (Muirhead's diphtheroid) had been obtained three times. This organism probably played a part in the symptomatology of general paralysis, but it was not asserted to be the cause. It was found in three other cases of doubtful general paralysis and in a fourth possible case another organism—a streptothrix—had been twice found. Finally, with regard to the part which the bacillus paralyticans played in the etiology of general paralysis the results of these researches were practically negative.—In the discussion which followed Dr. T. S. CLOUSTON alluded to the extreme degree of improvement which he had observed in the cases treated by Dr. Ford Robertson and Dr. McRae.—Dr. LEWIS C. BRUCE said that he had examined three of the cases so treated very carefully and two were undoubtedly cases of general paralysis. He had injected two true cases with 20 cubic centimetres of anti-rheumatic serum and they showed no reaction. He also injected 20 cubic centimetres of anti-bacillus coli and 20 cubic centimetres of polyvalent anti-streptococcus serum, and also without reaction. He then injected 20 cubic centimetres of serum obtained from Dr. Ford Robertson, and within 12 hours there was a reaction with a temperature of 99° F. Dr. Bruce had made numerous observations but had never been able to obtain any organisms from the blood of general paralytics.—Dr. DAVID LAWSON (Banchory) and the PRESIDENT made remarks, and the authors replied.

Reviews and Notices of Books.

Green's Encyclopedia and Dictionary of Medicine and Surgery. Vol. I., Aachen to Brain; Vol. II., Bread to Ear. London and Edinburgh: William Green and Sons. 1906. Vol. I., pp. 538; Vol. II., pp. 528.

AN encyclopædia is intended to afford detailed and more or less exhaustive information on the subject or subjects of which it treats, while a dictionary is essentially an alphabetically arranged index of words with brief definitions of their significance or meaning. Adopting some such general explanations of the words encyclopædia and dictionary, the editor, in his introduction, defines an encyclopædia of medicine as "a series of volumes containing extensive information on all the subdivisions of medical and surgical theory and practice," while, in his view, a medical dictionary, in the strict sense of the words, is "a list of definitions of medical and surgical words arranged alphabetically."

In this work an attempt is made to produce at once a dictionary and an encyclopædia—i.e., the general arrangement of the work is alphabetical but the descriptions appended to the words or terms discussed fall into two groups: first, comprehensive descriptive articles or monographs by various authorities, reprinted from "The Encyclopedia Medica" (1899–1904), on medical and surgical subjects of importance; and, secondly, brief descriptions or explanations of all the ordinary words used in connexion with medicine and its attendant sciences. These descriptions are written by the editor.

Judged by the two volumes before us we may say that the attempt appears to be a successful one. The various encyclopædic articles are well written, are conveniently arranged on a general plan, and are admirably adapted for rapid reference. Each begins with a brief summary or *résumé*, then a definition or an explanation of the scope of the subject follows, with a classification and a general discussion, including, where such are necessary, diagnosis, prognosis, and treatment. In regard to the directions for treatment these are concisely stated and definite instructions are given, including details of prescriptions or of measures recommended. In a few cases these articles are illustrated and the figures, diagrams, and plates given are clear and should serve a useful purpose in elucidating the text. The coloured plates of bacteria and of blood corpuscles are also good. In connexion with subjects concerning which much new work has been done since the appearance of "The Encyclopedia Medica" notes are appended in

small town in the Umballa district, had a death-rate of 90 per 1000 of its population from plague. In Jamke, a small town in the Sialkot district, a death-rate of 116 per 1000 from plague was registered.

In 1902 the Sanitary Commissioner reports that in the minor towns of the Ludhiana district the ravages committed were fearful. Raikot and Machiwara were almost decimated. Jagraon lost 11 per cent. of its population and Khanna no less than 14 per cent. In 22 villages the death-rate from plague ranged from 20 to 40 per cent. of the population. These death-rates, or depopulation of villages, are similar to those which are recorded as having occurred in some of the villages of the Bombay Presidency. There some of the villages lost 33 per cent. of their inhabitants. As is always the case in plague, some places escape lightly in one year while others are almost depopulated.

Since 1903 special reports on plague in the Punjab have been discontinued and in that year the administration of plague was handed over to the Inspector-General of Civil Hospitals, an officer whose duties in ordinary times are always of an onerous character and who could have no time to devote to this extra work. Owing to these changes the information is henceforth scanty. In 1904, however, there can be gleaned from the few remarks made by the Sanitary Commissioner, when treating of the vital statistics of the province, the havoc which the plague caused in some localities. Thus he says: "As an instance of the fearful increase in the mortality caused by plague, it may be noted that the death-rate of the district of Shahpur in April when plague was most virulent was *twenty-three times* higher than in August, by which time the disease had entirely disappeared. The total number of deaths in April in that district was 17,889, of which no fewer than 17,012 were ascribed to plague, as against only 781 in August, including one death from plague. The death-rate for Shahpur for April was *415 per mille per annum*." With this rate in the district bibliographies are very complete, that dealing with puerperal fever taking up some 75 pages, although it contains references only to the publications which have appeared since the year 1889. The sections dealing with puerperal fever dwarf all else in this volume. The disease is discussed in all its aspects with the most complete thoroughness. Dr. Walthard describes the general bacteriology and a special account of the gonococcus is given by Dr. Wildbolz. The main part of the description of the disease, including the pathological anatomy and the treatment, is from the pen of Dr. O. von Herff. The author (from the study of a large number of statistics) arrives at the conclusion which has been reached by practically all writers on this subject—namely, that the death-rate from puerperal fever, in spite of all the advances made in the prevention of the various forms of septic diseases in surgery, is at the present time practically stationary. He shows that the lying-in woman is safest when confined in a lying-in hospital and he further proves that the observance of strict antiseptic or aseptic precautions is a sufficient and certain preventive of the disease. We are glad to see the stress which is laid on the use of alcohol in disinfection of the hands, since the adoption of this substance for the purpose is still far from common even in well-conducted lying-in hospitals in this country, and we are convinced that it is of the utmost importance. No less important is the wearing of sterilised rubber gloves, but at the same time if such a practice is to lead to less care being taken in the proper sterilisation of the hands it can only result in disaster and disappointment. Indeed, it is a moot point which are the most dangerous—imperfectly cleansed hands or imperfectly cleansed rubber gloves. It must always be remembered that whilst the general surroundings and the atmosphere, so to speak, of a surgical theatre or of the lying-in ward of a well-conducted hospital are directly conducive to the strict carrying out of antiseptic precautions the surroundings in the majority of confinement cases in private practice are far from encouraging such observances. The treatment of cases of septic infection is very fully considered, although we must confess to some disappointment on reading this portion of the article. It is impossible to come to any other conclusion than that treatment is of little avail, and if prevention fails then the medical attendant is often only too helpless to avert a fatal issue to the case. When we consider the mortality rate of the disease the question as to whether any one of the various methods of treatment advocated really has much effect in diminishing the danger becomes a very difficult one to answer satisfactorily. The teaching laid down as to the uselessness of the administration of alcohol in these cases is directly opposed to that of most writers but is in accordance with the opinion of some medical men as to the harmfulness of alcohol to the body in any conditions, whether it be those of health or disease. Curetting, we are glad to see, is strongly condemned and Dr. von Herff concludes that hysterectomy in these cases is usually of no avail. The question as to whether any good is to be expected from the excision of the pelvic veins in puerperal pyæmia receives the full consideration which it deserves. The opinion expressed, with which we are in accord, is that this operation is as a rule not indicated on account of the difficulties experienced in deciding in what particular case it should be performed and the further difficulty there often is in determining on which side the veins are affected. The removal of the uterus is required only in cases where it contains a sloughing fibroid or where there is definite evidence of an abscess in its walls.

These two volumes are amongst the best of the whole series and are in every respect most complete and helpful. The work constitutes a series of monographs written by eminent authorities and, we imagine, will long remain without any possible rival in this sphere of medicine. It is indispensable for the teacher and should be in every large medical library.

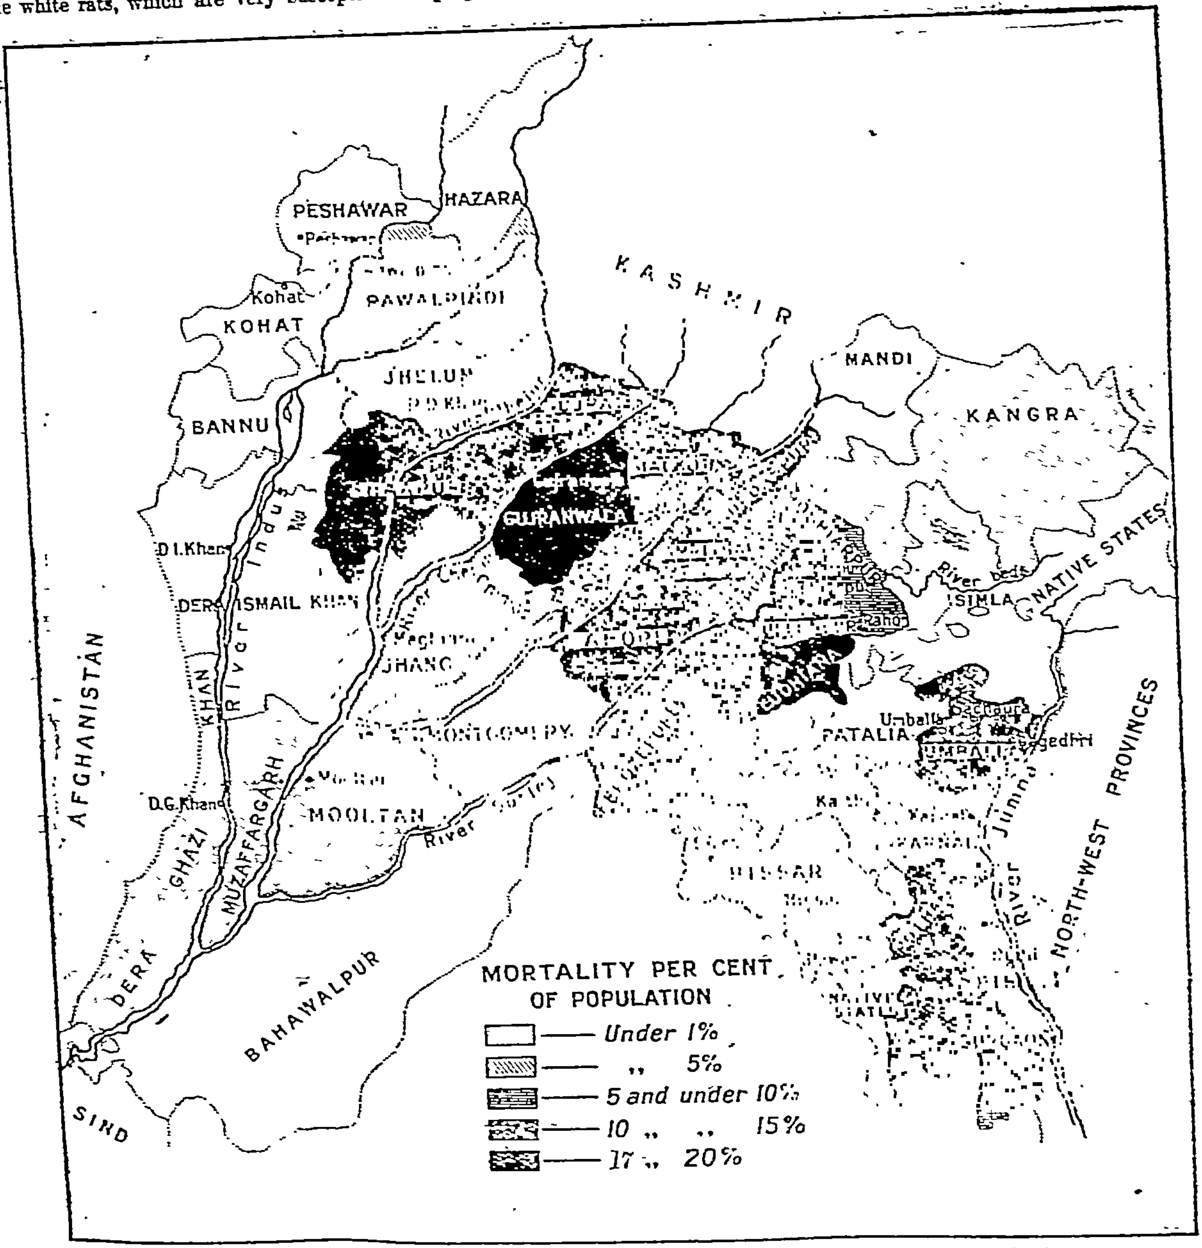
Gall-stones and Diseases of the Bile-ducts. By J. BLAND-SUTTON, F.R.C.S. Eng., Surgeon and Lecturer on Surgery to the Middlesex Hospital. With 47 illustrations. London: James Nisbet and Co., Limited. 1907. Pp. 233. Price 3*s.* 6*d.* net.

THIS book commences with a short anatomical and physiological account of the bile-ducts and the bile and all of this chapter is interesting and most of it is important. Then come sections on infections of the bile-ducts and gall-bladder. A good account is given of gall-stones and of their results. A chapter on cancer of the gall-bladder follows, and then comes a chapter on the effects of some forms of pancreatic disease on the excretory apparatus of the liver. The signs and treatment of cholelithiasis are given at some length and a chapter on the mortality of operations for the relief of gall-stones closes the book. We have described the contents of the volume to show the reader that, though the book is small, it contains a good deal. The style is simple and the addition to each chapter of references to works dealing with the subject enables the reader to look up the matter more fully if he wishes. We are pleased with the book and though there are many controversial points dealt with, about which we are not fully in accord with the author, it should prove of value to senior students and to those in practice. This volume is the first of a new series of books called Modern Clinics.* If the later volumes are as good as this the series will have justified its existence.

LIBRARY TABLE.

The Practical Medicine Series. Under the general editorial charge of GUSTAVUS P. HEAD, M.D. Vol. VIII., Materia Medica and Therapeutics, Preventive Medicine, Climatology, Forensic Medicine. Edited by G. F. BUTLER, M.D., H. B. FAVILL, M.D., NORMAN BRIDGE, M.D., D. R. BROWER, M.D., and H. N. MOYER, M.D. Series 1906. Chicago: The Year Book Publishers. Glasgow: G. Gillies and Co.—In this work the collaborators in the department of Materia Medica and Therapeutics state that there has been a widespread demand for more simplification and precision in the armamentarium and that the use of crude galenical preparations is giving way to active principles and remedies of known and unvarying strength. They regret that the contributions on the subject of psycho-therapy, or suggestive therapeutics, have been meagre during the year. They write, "Physicians should inculcate hope in the degree of optimism; their lives should radiate love, hope, cheerfulness, and optimism." In the section on Preventive Medicine the suggestions on the protection of children from contagion are valuable, as are indeed the directions for the conduct of the tuberculous as given by Rochester. The following is a brief summary: 1. The consumptive should kiss no one and no one should kiss the consumptive on the mouth. 2. The consumptive should never lend his handkerchief to anyone or borrow a handkerchief from anyone. 3. The eating and drinking utensils of a consumptive should be thoroughly boiled after he has used them. 4. During the act of coughing he should hold before his mouth a piece of cheese cloth or gauze or other material, which may be burned or boiled. 5. The sputum should be discharged into a piece of cheese cloth or gauze, so folded that the sputum may be turned in and completely covered. Such piece of gauze should be put into a proper receptacle until it is time to take it out and to burn it. 6. The sheets, pillow cases, night-clothes, and underclothing of consumptives should be boiled for half an hour before being washed. Under the heading of Climatology the question as to whether the sanatorium treatment of pulmonary tuberculosis is worth while is answered strongly in the affirmative. Among the

Dr. Ashburton Thompson is the champion, has recently eceived very valuable support in its favour from the very mportant experiments made by the Indian Plague Commission and which are the outcome of certain researches by Captain W. G. Liston, I.M.S., to whom much credit is due for his excellent work in this direction. These experiments established first the accuracy of Simond's and Gauthier's and Raybaud's experiments as to the power of infected fleas from plague rats causing plague in healthy rats: 61 per cent. of the white rats, which are very susceptible to plague, and 52 per cent. of the Bombay rats experimented on contracted plague by the transference to healthy rats of fleas from infected rats. Similarly, guinea-pigs allowed to run free in plague houses in many instances attracted a large number of fleas, most of which were rat fleas, and 29 per cent. of the guinea-pigs contracted plague. Animals in cages protected from fleas by a layer of "tanglefoot" did not contract plague, while animals in cages not so protected developed plague to the extent of 24 per cent. Out of 247 fleas caught on the "tanglefoot," 60 per cent. were human, 34 per cent. were rat, and 6 per cent. were cat fleas. Plague-like bacilli were demonstrated in the stomach contents of one out of 85 human fleas dissected and of 23 out of 77 rat fleas. The commission carried the observations a stage further, and by the transference of infected fleas from guinea-pigs started an epidemic of plague among healthy guinea-pigs which was maintained by the introduction of fresh infected fleas.



Map showing incidence of mortality from plague from 1901 to May 11th, 1907, on British territory in the Punjab according to districts. Scale 100 miles to the inch.

That the flea is an important agent in spreading plague from rat to rat and in the maintenance of rat epizootic is evident from these experiments. The rat flea, variously named by different observers Pulex cheopis, Pulex murinus, and Pulex pallidus, and commonly found on the Mus rattus was the active agent in the transfer of the disease from rat to rat and from rat to guinea-pig. To the extent to which the Pulex cheopis is an agent in keeping up the epizootic in the rat, it will account for the epidemiology of plague, but it is not a necessary deduction from this that Pulex cheopis plays the same active part in the transfer of the disease from the rat to man as it does from rat to rat, though it may be credited with an indirect influence in the maintenance of the disease in man owing to its being an active knot are temporarily held out of the way behind two flat springs attached to the ring handle. It will be seen from the illustration that any long object caught in the forceps is necessarily surrounded by this loop so that drawing the loop close and tying the second half of the knot secures the artery. The inner aspect of each blade has a shallow recess in the central portion and is also provided with a transverse groove which might serve for holding a needle. In other respects the forceps has a great resemblance to the ordinary English artery forceps named after the late Sir Spencer Wells. It is made in two sizes—five inches long (price 6*s*. 6*d.*) and seven inches long (price 8*s*. 6*d.*). The London agents are Messrs. Allen and Hanburys, Limited, 48, Wigmore-street, W.

A NEW PORTABLE OPERATION TABLE.

IT is not from a wish to add another portable table to the long list of those already in existence that I have devised the one here depicted. My reason for planning this table, and having it made, is that there are, in my opinion, grave defects in all those at present on the market; this one, however, has at least the essential attributes of a good operation table in a portable form and the following points may be referred to. 1. It is light, weighing about 35 pounds (i.e., about the same weight as an ordinary Jordan Lloyd's flat wooden table). 2. When folded, the size in a canvas cover is 40 by 23 by 7½ inches and it can be put up or taken down in a few seconds. 3. It is made entirely of steel. 4. It is absolutely rigid. 5. Any of the surgical positions can be obtained. The method of obtaining the Trendelenburg position is a new one and very simple. As will be seen from Fig. 1, two thin wire hawsers pass round cylinders underneath the body of the table, and are controlled by the handle at the right hand of the anæsthetist, who can thus turn the table into the Trendelenburg position in a moment. The patient is kept from sliding down by shoulder props or anklets (which I prefer), according to the fancy of the operator. It is important to notice, too, in regard to this position that the table turns on the central axis and is not raised in the middle portion to the detriment of the operator, a fault common to almost all portable tables. The lowering or raising of the end of the table alone, as shown in Figs. 2 and 3, is also accomplished by a new and simple device, which, as with the method of obtaining the Trendelenburg position, does away with the necessity of any rack.

FIG. 1.

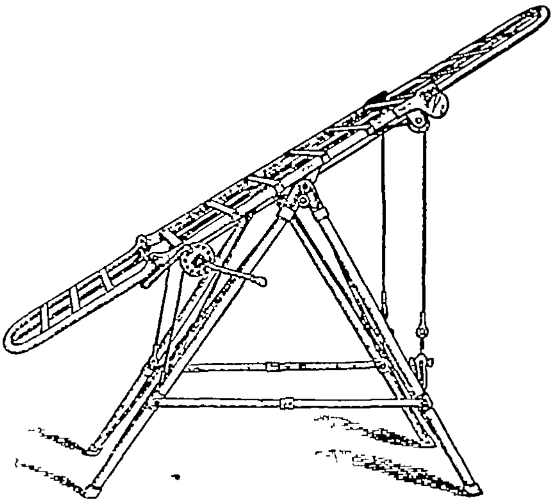


FIG. 2.

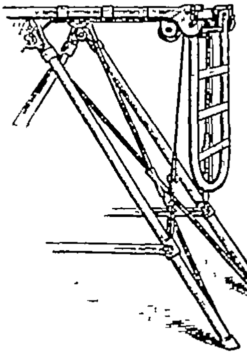

FIG. 3.

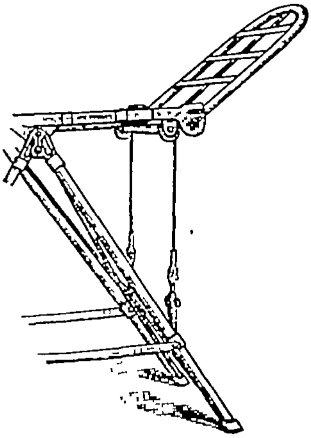


I may add, lastly, that it is the cheapest metal table of the sort on the market. I venture to hope that it will be specially serviceable to gynæcologists, to whom the Trendelenburg position is essential.

Messrs. White and Wright, 93, Renshaw-street, Liverpool, have made the table for me, and I am much indebted to them for having conducted expensive experiments and for having so faithfully carried out my instructions.

W. BLAIR BELL,
Assistant Gynæcological Surgeon, Royal Infirmary, Liverpool.

A NEW TOURNIQUET.

THIS tourniquet is very simple in its construction, consisting of only two parts,—namely, a stout vulcanised indiarubber tube of any desired length and a cylindrical ring to which two hooks are jointed. The tube is passed through the ring and round the injured limb, after which its ends are securely clamped by pulling them into the angle at the bend of the hooks. The tension is easily adjusted and controlled, being regulated from both ends and not from one end only as in many tourniquets. So long as the indiarubber remains in good condition the purpose would be served, but this substance is, of course, liable to deteriorate from a variety of causes. The new tourniquet is made by Messrs. S. Maw, Son & Sons, Aldersgate-street, London, E.C., who have called it the "Securitas." The price is 4*s*. 9*d*.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual election of members of the Council was held at the College in Lincoln's Inn Fields on July 4th. There were four vacancies and seven candidates: Mr. H. W. Page, Mr. C. W. Mansell Moullin, and Mr. F. S. Eve were applying for re-election; and Mr. Charles Higgens, Mr. W. Bruce Clarke, Mr. Charters J. Symonds, and Mr. W. D. Spanton were applying for election. The polling commenced at 3 o'clock and was closed at 5 o'clock. The counting of the votes lasted an hour and a quarter and the result was as follows:—

	Number of votes.	Plumpers.
C. J. SYMONDS	452	26
W. BRUCE CLARKE...	413	52
C. W. MANSELL MOULLIN	403	6
F. S. EVE	388	3
H. W. PAGE	349	11
W. D. SPANTON	348	34
C. HIGGENS	234	10

The PRESIDENT (Mr. HENRY MORRIS) announced the result and declared that Mr. Mansell Moullin and Mr. Eve were re-elected and that Mr. Symonds and Mr. Bruce Clarke were elected members of the Council.

It was the heaviest poll that has ever been taken. In all 892 votes were received, 873 being received through the post, and of these two were disallowed as the signatures of the voters were not witnessed and three were received after the opening of the poll; one was disallowed also because the voting paper was blank. 14 Fellows voted in person.

Mr. T. Crisp English and Mr. Willmott H. Evans acted as scrutineers.

ON Friday, July 19th, Lady Duckworth-King will open the new electrical department of the Royal Devon and Exeter Hospital presented by Mrs. Sanders in memory of her husband and son, both of whom were formerly Presidents of the hospital.

observed in the out-patient department. By such observations, spread over the last three and a half years, the writer has been able to take a broad survey of the subjects included under the title of this lecture, some results of which are brought to notice in this communication. At a later date the writer hopes to present more of his observations.

With the aid of my clinical assistants, especially Mr. J. Howell Evans and Dr. H. Irving Pinches, a survey was made of the herniæ in the out-patients at Great Ormond-street who attended on my days. To these two gentlemen I owe many thanks for the work which they have performed. When we had completed about 700 observations it was felt that a most important factor had been omitted and that the whole work had to be re-done. The results of this collective investigation of the first series are summed up as follows:—

TABLE I.—*First Series of 700 Observations.*

	Per cent.
Right inguinal herniæ	38 3
Right and left inguinal herniæ	10 8
Right and left inguinal and umbilical herniæ	8·0
Right inguinal and umbilical herniæ	12·0
Left inguinal herniæ	10·6
Left inguinal and umbilical herniæ	2·7
Umbilical herniæ	16 2
Epigastric herniæ	0·9
Femoral, right and left	0 15
Complicated by a ventral hernia between the divaricated recti	14 3
Single herniæ	66·0
Multiple herniæ	34·0

This table includes all the ordinarily recognised herniæ, but no account is taken of the median ventral hernia between the upper parts of the recti abdominis muscles, except that it was noticed casually that 14·3 per cent. were accompanied by this ventral hernia. But as more and more observations were made, the writer, becoming convinced of the first-rate importance of this missing factor, terminated the investigation after 700 observations had been made and commenced a new inquiry on a wider plan executed by a larger number of helpers whose observations were unaffected with the writer's particular opinions on this subject. All concerned in this second investigation were ignorant of the figures and fallacies of the first except myself, so that their observations were unbiassed.

One very remarkable fact was shown by the first investigation—namely, that multiple herniæ were far more frequent in children than they were in adults. Single herniæ were found in 66 per cent.; multiple herniæ in 34 per cent. This is suggestive either of the multiplicity of congenital sacs in one subject or of one factor, common to all, which was the cause for the herniæ present. But it was obvious that this survey was very incomplete because it had omitted to take into consideration, as almost all previous authors have, the hernial protrusions between the divaricated recti. In order to obtain in the second and larger survey results independent of my private views I asked many to help. To them I must acknowledge my grateful thanks: Dr. A. F. Stabb, obstetric physician to St. George's and Queen Charlotte's Hospitals; Mr. G. E. Waugh, one of my surgical colleagues at Great Ormond-street; Mr. H. A. T. Fairbank, another of my surgical colleagues at Great Ormond-street and attached to Charing Cross Hospital; Mr. Howell Evans of Great Ormond-street and the Children's Invalid Aid Association, and Dr. Irving Pinches, my clinical assistants; Mr. Duncan C. L. Fitzwilliams, casualty officer to Great Ormond-street; Mr. S. R Gibbs, Mr. H. T. Gray, and Dr. R. J. H. Cox of St Thomas's Hospital; Dr. Alice N. Vowe Johnson of the Lambeth Schools Infirmary; and particularly Mr. M. Cursham Corner, for a large and invaluable series of observations on the newly-born.

Like herniæ in other parts of the body the ventral one between the divaricated recti is not necessarily obvious unless the abdominal muscles are thrown into action, such as is done when obtaining the impulse on coughing in adults. To do this in children requires some little skill and tact, so that the observations are not often made. The most generally applicable method is to place the child on its back on a table or its mother's lap: often it will begin to cry at once when the ventral hernia will become obvious. If this is not so its abdominal muscles may be stimulated by a finger or the handle of a pen. Should this fail, as it often does, the child's head must be supported with one hand, which at first raises it and then allows it to fall sharply backwards two or three inches. Whilst this is being done the observer watches the abdomen for the momentary contraction of the muscles, a carinate projection appearing above the umbilicus if a median ventral hernia is present. In difficult cases other means may be required to demonstrate the protrusion. If care is taken I believe that this hernia will be found more frequently than is indicated by my collective investigation of 2600 cases when it was noted in 24·21 per cent. In fact, one knows that the more carefully the observations are taken the more frequently will a median ventral hernia be found. For instance, two who helped me found the median ventral hernia present in 63 per cent. and 21 per cent. respectively, showing that the results vary with the observer, possibly depending on both the care and the time spent in making them.

In his text-book on Surgery Sir Frederick Treves has stated that the sac, its coverings, and its contents are the three essential parts of a hernia. Recognising that a hernial sac does not always contain any viscera a hernia may be recognised as being formed of a peritoneal protrusion which has separated some of the structures which form the abdominal walls; the formation of the peritoneal sac may or may not be accompanied by some abdominal viscus or viscera. Naturally these protrusions occur at the weaker regions of the abdominal walls: the inguinal, femoral, and umbilical regions. When the recti muscles are divaricated the linea alba is stretched and thinned, allowing the peritoneum and perhaps the omentum and intestine to bulge forward. This bulging constitutes a true hernia having all the essential parts, and as it is found almost exclusively in children it is a peculiar character of their herniæ. Because it was neglected, as it has been by most observers, my first series of observations, which extended over two years and more, was invalidated and the second series was undertaken to remedy the defect. As with all other herniæ, the median ventral hernia between the divaricated recti may be congenital or acquired. Differing from inguinal and femoral herniæ in the sac having no neck and communicating widely with the abdomen, its presence is demonstrable with its first appearance, which need not be so in cases of the others mentioned. The observations of Dr. Stabb and Mr. Cursham Corner have shown that it is a very uncommon, but not unknown, condition to find in the newly born; the former only found it once in 122 observations. Hence there is little evidence in favour of its congenital origin. How, then, can it be acquired? As any given child can only digest and absorb a certain amount of nutriment, which varies with its every mood, any residue, whether an excess of good food or the remains of an indigestible meal, will go bad and ferment in the intestines unless expelled. For details of its fermentation I must refer the reader to my lecture on Some Surgical Results of Improper Feeding, published in the *Clinical Journal*, June 27th, 1906, pp. 171–176. In this place it need only be stated that, amongst other products, gases are formed which distend the intestines, raise the intra-abdominal pressure, and, if not quickly got rid of, will dilate the abdomen, separating the component parts of its walls. To particularise the subject of this lecture, the ventral herniæ between the upper parts of the divaricated recti appear for two reasons: first, as the direct result of the increased intra-abdominal pressure; and, secondly, as the indirect result of the continuance of the raised pressure upon the growth of the tissues of the linea alba.

The incidence of this ventral hernia at the different ages of life is of great interest. I am indebted to Mr. Cursham Corner for his observations in the early stages of life. He remarked that, on the average, the umbilical cord separated on the fifth day, when there was invariably some bulging of the umbilical cicatrix which lasted until the eighth day, when the scar became firm. The size of the bulging was dependent upon the length of cord left proximal to the ligature. He made 201 observations on children between birth and one year of age and found a median ventral hernia between the divaricated recti in 18·5 per cent., being more frequent amongst older infants. At Queen Charlotte's Hospital Dr. Stabb only found one case (in an infant one day old) of bulging between divaricated recti amongst 122 infants varying from one day to 39 days old. Amongst other observers at Great Ormond-street bulging between divaricated recti was found in 34 per cent. in infants under six months of age and in 58 per cent. between that and one year. These figures may be arranged as follows:—

	Per cent.
Queen Charlotte's Hospital (1–39 days)	0 8
East End Mothers' Home (1–365 days)	18 5
Great Ormond-street (under 6 months)	34·0
Great Ormond-street (6–12 months)	58·0

Reticence to Patients.

AN unfortunate young man, assistant to a druggist at Altrincham, is reported to have committed suicide a few weeks ago in consequence of having been told by his medical attendant that he was the subject of pulmonary tuberculosis. As one result many of our brethren of the non-medical press, not to speak of their "Constant Readers" and other correspondents of various denominations, have been much exercised in their minds over the question whether it is right or desirable for a medical practitioner to warn a patient of the dangerous character and probably fatal termination of an illness. As thus stated, like its famous precursor, "Which came first, the bird or the egg?" the question has the great advantage of being insoluble, and hence of admitting of unlimited discussion, terminating always in the same *impasse*. What is best to be done in any particular case is a matter of discretion and of circumstances, as to which no general rule can possibly be laid down. The supposed discretion will sometimes be indiscreet, the circumstances will sometimes be wrongly interpreted, and harm must occasionally follow, perhaps more often from undue candour than from improper reticence. Queen VICTORIA'S first Prime Minister, Lord MELBOURNE, was much addicted to the inquiry, "Couldn't you have let it alone?" and a similar inquiry is one with regard to which everybody who feels inclined to action, and especially to action beyond the strict limits of professional or personal duty, may well pause and put to himself before, rather than after, any irrevocable word is uttered. Many authentic cases are on record in which an announcement of probably impending death so precipitated the event as to render the warning useless; and many also in which such an announcement has been received with tranquil resignation, or even with absolute indifference. We recall one instance in which the practitioner concerned was actuated rather by theological than by medical considerations and in which, towards the close of a year, he exerted himself to impress upon a patient that he was not likely to see the year which was to follow. At the next visit the patient recurred to the subject, said that the conversation had rendered him uneasy, that there was a matter to which he ought to attend, and that he could sign his name if the medical man would have the kindness to write at his dictation. A ready consent was given, writing materials were procured, and the sick man dictated a letter to his bankers instructing them not to pay his club subscription on the approaching first of January without further orders. We do not know how long he survived, but it seems practically certain that the knowledge imparted to him did not hasten his decease.

In cases of acute illness there are, we presume, two totally different sets of arguments which might be urged by different people in support of the view that the sick person should be told of the existence of serious danger to life. The first of these would rest upon theological, the second upon purely secular, considerations; and with regard to both the medical practitioner has only to consider the immediate bodily welfare of the patient. The duty and business of the physician is to preserve or to prolong life, and to the discharge of this duty every other consideration should give way. If manifest mental anxiety were present as a cause of depression it should, if possible, be relieved, whether it were dependent upon mundane or ultramundane cares, and the sick man, if strong enough and intelligent enough, might be advised either, in the words of the liturgy, to send for "some discreet and learned minister of GOD'S Word and to open his grief," or to send for some judicious lay adviser, by whom his worldly affairs could be placed in the best train and reduced to the best order that time and cirumstances might permit. And either advice might be given, generally speaking, without risk of injury, not as a sentence of death, but on the sufficient ground of the always uncertain issue of serious illness and in order, as a measure likely to contribute towards recovery, to relieve so far as possible any distress of mind to which the sufferer might be a prey. Excepting in novels, however, the conditions described will only seldom be encountered. A patient who is in danger of death owes that danger to definite physical changes in the solids or fluids of his body, changes which generally entail incapacity either for clear perception or for sustained thought, and which afford a very complete protection against emotions which might be injurious if they were in active operation. It is not until the danger has passed away that there is likely to be any consciousness of its extent or character or any manifest dread of the consequences which it might have entailed.

The suicide at Altrincham appears, however, to have been occasioned by knowledge of the probable issue of a chronic illness, and it is not too much to say that it must have been the outcome of mental conditions of a somewhat exceptional kind. It was a practical reassertion of the dictum of the Stoic philosopher who said that if his chimney smoked he would open a window and that if the smoking continued he would open the door of his house and go out. The patient deliberately chose immediate death as an alternative to death reached only by the way of tedious illness; and his choice, from the Stoic point of view, was not unreasonable. But this point of view, in our day, is only met with as an occasional survival and need hardly be taken into account as a guide to the ordinary conduct of practitioners; while it is manifest that the sole reasonable hope of curing many chronic diseases must depend upon a completeness of submission to medical advice which, as a rule, can only be secured by an equally complete realisation of the true character of the issue. How many hundreds of sufferers from tuberculosis, from diabetes, from syphilis, from cancer, throw away their lives either because they are not made fully to understand the alternatives before them or because they are induced by incredulity to stray from the path of safety? A woman with a lump of the size of a marble in her breast will not be saved by being told that it would be "better for her" to consent to its immediate removal, but only by being convinced that nothing but immediate removal will afford any reasonable prospect of the preservation of her life. How many people are there who in an early stage of pulmonary tuberculosis would submit to the discipline necessary for the fulfilment of any prospect of cure if they were only told that they were "delicate" and if the real nature of

ON THE TREATMENT OF LUPUS.

BY DR. MED. DREUW, M.D. BERLIN.

(*Translated from the German by* R. CRANSTON LOW, M.B. EDIN., F.R.C.P. EDIN.)

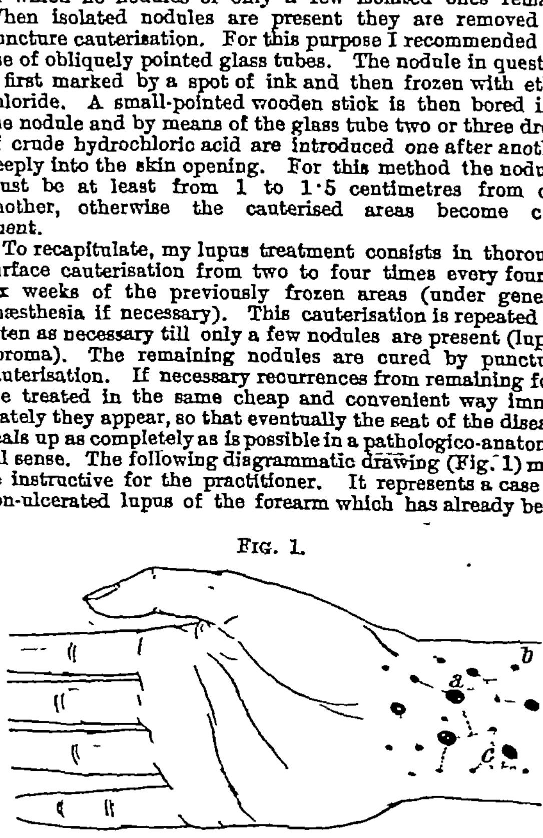
THE methods of treatment in lupus which are in general use at present are the following: (1) physical (Finsen light, Roentgen rays, and radium); (2) chemical (caustics); (3) mechanical (surgical methods); and (4) internally acting substances (cantharidin, tuberculin). There is no single method which can definitely cure every case of lupus so that no recurrence will take place. Therefore, as was specially drawn attention to at the International Dermatological Congress in 1904,[1] the one-sided method of applying the same treatment in all cases of lupus, and in all stages of a given case of lupus, is not to be recommended. But according to the prominent symptom, the surgeon should choose out of the different methods the one which is specially indicated and suited for the object in view. The treatment of lupus by physical means such as the Finsen light or the *x rays* requires so much time and such costly apparatus that these necessarily are only within the reach of a few specialists. For the majority of practitioners these methods are impossible unless they are associated with some public or private institution. A great number of specialists and almost all practitioners are therefore to-day still dependent on methods which are simpler and cheaper in their application. Every method for the treatment of lupus which can be used by the practitioner himself and which is handy and easy of application is to be heartily welcomed. The practitioner should be in a position to attack on its first onset a disease such as lupus, which causes so much disfigurement.

I introduced over two years ago a method for the treatment of lupus[2] which places the general practitioner in a position to treat it cheaply, easily, and with success. The method is as follows. The lupus patch which is to be treated is frozen by means of ethyl chloride (or by carbonic acid gas[3] if a deeper effect is desired) till it is snow-white. Over this frozen surface crude hydrochloric acid is rubbed thoroughly and with a certain degree of force. According to Unna it is advantageous to saturate this crude hydrochloric acid with chlorine. The acid is applied in the following way. Cotton-wool is wound round one end of a small wooden stick of about the size of a penholder; this is dipped in the crude hydrochloric acid and rubbed on the frozen surface, pressing slightly, till the nodules become of a greyish-white colour (re-action). This greyish-white colour occurs first where nodules are and then in the skin surrounding the nodules. In this way a large surface can be treated at once by a succession of applications of the caustic. If the patch is very large it is best to administer choloroform. The spots are then similarly thoroughly frozen by preference with carbonic acid gas and then by the above-mentioned means the crude hydrochloric acid is energetically rubbed in. This freezing and cauterisation under general anæsthesia is especially suitable (1) in lupus multiplex and lupus exulcerans; (2) in lupus of the mucous membranes, the nasal cavities, the lips, and tuberculous abscesses and fistulæ (cauterise from six to eight times in rapid succession); and (3) where the freezing is not well borne by the patient (e.g., nervous and sensitive patients) or where very energetic cauterisation is necessary—e g., in tuberculous ulcers, lupus hypertrophicus and verrucosus.

In treating the nasal cavities during the anæsthesia all the tuberculous tissue is scraped away with a sharp spoon and the bleeding is stopped with adrenalin. The posterior nares should be previously plugged. Then the nose is thoroughly cauterised eight or ten times with the wooden sticks dipped in hydrochloric acid. So many applications are necessary because the hydrochloric acid becomes diluted and neutralised by the blood. The crusts which are formed in the nose are removed every two or three days by softening them with oil and douching the nose. The after-treatment of all cauterised lupus areas consists in the application immediately after the cauterisation of a disinfectant and astringent powder which is dusted on with a piece of cotton-wool. I have found eugoform, which is a condensation product of guaiacol and formalin, the best. A bandage is usually unnecessary. Instead of the powder after a few days zinc gelatine or zinc sulphur paste may be applied. One or two days after the surface cauterisation a brown scab forms, which falls off in from two to four weeks. Together with the scab the most superficially lying nodules are cast off, while the deeper ones still remain as such and after four weeks can be recognised by the diascope[4] as brown points. In cases where several nodules are present close to one another from one to four applications of this surface cauterisation are made every four or six weeks. In the course of from three to six weeks a fairly extensive lupus is replaced by a tissue (lupus-fibroma) which is covered with epithelium and in which no nodules or only a few isolated ones remain. When isolated nodules are present they are removed by puncture cauterisation. For this purpose I recommended the use of obliquely pointed glass tubes. The nodule in question is first marked by a spot of ink and then frozen with ethyl chloride. A small-pointed wooden stick is then bored into the nodule and by means of the glass tube two or three drops of crude hydrochloric acid are introduced one after another deeply into the skin opening. For this method the nodules must be at least from 1 to 1·5 centimetres from one another, otherwise the cauterised areas become confluent.

To recapitulate, my lupus treatment consists in thorough surface cauterisation from two to four times every four or six weeks of the previously frozen areas (under general anæsthesia if necessary). This cauterisation is repeated as often as necessary till only a few nodules are present (lupus fibroma). The remaining nodules are cured by puncture cauterisation. If necessary recurrences from remaining foci are treated in the same cheap and convenient way immediately they appear, so that eventually the seat of the disease heals up as completely as is possible in a pathologico-anatomical sense. The following diagrammatic drawing (Fig. 1) may be instructive for the practitioner. It represents a case of non-ulcerated lupus of the forearm which has already been treated and which shows by the diascope perceptible nodules; five of these nodules (darkly marked in the drawing) lie deep in the cutis (cf. illustration), while the remaining ones are close under the epidermis. Every effective chemical and physical treatment destroys the superficial nodules and the superficial connecting bridges first. Only in the later treatment can the deeper tuberculous tissue be affected. In the course of treatment more and more of the tuberculous deposits disappear to be replaced by new connective tissue. Finally, only isolated lupus nodules, which are recognisable by their brown colour under the diascope, are to be seen. These are then treated in any suitable way till they are no longer visible and in their

FIG. 1.



The larger dots (a) represent deep-seated nodules in the cutis. The smaller dots are mere superficial nodules (b) which lie just under the epidermis. The dotted lines (c) represent connecting bands of tuberculous tissue (cf Fig. 2).

[4] Diascopy depends on the following *facts* If pressure is made with a glass spatula, a glass pleximeter, or a microscope slide on the normal skin it becomes quite pale because the blood is pressed out of the capillaries. In lupus, instead of fibrous and elastic tissue and capillaries, there are collections of cells (lupus nodules) which lie closely packed together and fairly sharply limited in the cutis. These cells appear through the glass as brown areas, whilst the surrounding bloodless areas are light in colour. It is best to use a glass pleximeter and to apply some fatty material to the skin beforehand.

vagaries under the heading of superstition. We agree with Mr. Haggard in giving that designation to the credulous support which is given to the claims of quacks and patent medicines, although we are not sure that he would not have done better to label antivaccination as the result of sheer selfish and reactionary obstinacy. It is certainly begotten of influences a long way removed from that blend of science with imagination which we set out to discuss.

Annotations.

"Ne quid nimis."

THE GOVERNMENT AND VACCINATION.

Already there are signs that the Vaccination Bill and the General Order associated with it find no favour with those who are immediately concerned with their execution. From vaccination officers there have come a sheaf of published denunciations, while the opinions of public vaccinators, if less freely expressed, have been equally emphatic in their condemnation. The Bill has, indeed, little to excuse it, not even a "mandate." It cannot be claimed that more than a relatively insignificant proportion of the inhabitants of this country are genuinely opposed to vaccination. On the other hand, a considerable number of persons, for various trivial reasons and without conviction, are willing to dispense with it. It is to these ill-informed and wavering persons that the facility of exemption by simple declaration will chiefly appeal. For them a too indulgent administration has made provision accordingly. We cannot admit the wisdom of such a course. If vaccination had nothing to do with the public health or any other matter of importance so complaisant an attitude might be justified. Since it is the only safeguard against small-pox known to science, a proved and trustworthy remedy, and on these points there can be no question, then the case is entirely different. To tamper with such a fact as this is to play with fire, for the issues of misapprehension must be disastrous. It is impossible to reconcile with any due sense of the importance of these issues the rapid, almost casual, manner in which this Bill passed through its second reading. The principle of compulsory vaccination has never been condemned or even seriously indicted. On the contrary, it has been accepted and approved by the great majority of the population as a sanitary necessity. Yet a mere handful of gentlemen, one-fifth of the membership of the House of Commons, few with expert knowledge, have been permitted not only to threaten but, unless their decision be reversed, even to terminate its existence. This, moreover, without the slightest reference to public opinion. Surely the inherent faults of party government and the unreality of our so-called representative system were never more graphically exhibited than in this case. We sincerely trust that a measure so little desired by the country and so undesirable on sanitary grounds will not survive the later and calmer judgment to which it is certain to be subjected in both Houses of Parliament. The General Order, in so far as it is new, is a somewhat crude production. That part which relates to the position of public vaccinators alters nothing save the fee, some slight apparent concessions having little real significance. The amount and character of the work are unchanged, but the fee in large towns is reduced by one-half, and in smaller towns and in country districts by nearly a third. The public vaccinator is thus made to accept a much reduced remuneration for his services and incidentally to undersell his brethren engaged in private practice. At the same time, two different standards of payment are adopted—a proceeding which will not only mar the simplicity of administration but will create an invidious distinction which in many cases cannot be justified either on the plea of distance traversed or of professional preoccupation. There are indications that all boards of guardians do not view the proposed reduction with equal favour and their uncertainty with regard to it will not be lessened by the circumstance that under the terms of the Order the whole responsibility for this alteration will rest on them. If the prospect before public vaccinators is not cheerful that of vaccination officers is positively alarming. At present four months are allowed in which a parent may obtain exemption. If at the end of that period he shall not have done so and his child remains unvaccinated the vaccination officer must take steps to have the vaccination performed. Under the new Order this officer will have to notify the parent *three weeks earlier*, stating that in default of "some legal excuse for non-vaccination" he must request the public vaccinator to vaccinate in due course—i.e., after a month has elapsed. He will also "be glad to be informed" if the parent "proposes some other arrangement for the vaccination." He is thus made to come almost as a suppliant and practically to remind the parent that only one month remains in which to claim exemption—a virtual surrender of his office in favour of an opposite policy. The vaccination officers have applied in vain for some compensation for the loss of income which they are certain to incur, or for some fixed arrangement as to salary. Not even are they to be allowed a small fee for their suicidal efforts in notification. Naturally as a body they feel aggrieved and they have in mere self-defence been driven to protest. The net result of these various legislative and administrative changes must be the discouragement of vaccination throughout the country. It is possible that this result may be brought about, and thus by rash interference with an Act which was working admirably and with very general acceptance, and by mere unsteadiness in administration that public security which is the fruit to-day of many years' experience and care may soon be broken down. Instead of it will come uncertainty, distrust, and the danger of epidemic. We have only to let go our present system of business-like efficiency and to adopt some such policy of indifference as is now proposed. Whether and whither that policy will be suffered to lead us will greatly depend upon the judgment exercised by Parliament and by boards of guardians in dealing with this important question of compulsory vaccination.

THE LEAGUE OF MERCY.

Very effective support is afforded to the King's Hospital Fund by the League of Mercy, over which T.R.H. the Prince and Princess of Wales preside as Grand President and Lady Grand President, and as such take a most active interest in the welfare of the league. This was again shown on July 8th, when they held a reception in Marlborough House of the presidents and lady presidents, followed by a garden party, to which many vice-presidents and members of the league were invited, and at which the Grand President distributed the Order of Mercy to those ladies and gentlemen to whom its award had been sanctioned by His Majesty the King, the Sovereign of the Order. Many prominent members of the medical profession were invited to be present. The work of the league can best be indicated by a quotation from the Prince's speech to the presidents. "The operations cover a larger area than before, and the sum of £18,000 which has been handed over to the King's Fund is £3000 more than was contributed in the previous year. It is very satisfactory to find that in the eight years of the league's existence £79,000 has been given to the hospitals through the medium of the King's Fund, and I think we may safely infer that one of the principal objects of the League of Mercy—namely, the encouragement of personal service on on the normal skin and tuberculous tissue without subsequent cauterisation Juliusberg writes :—

> From another point of view I made further experiments, as Dreuw had already reported, with the combination of freezing with ethyl chloride and then application of crude hydrochloric acid. The treatment was the same as that recommended by Dreuw with this exception, that ethyl chloride was replaced by carbonic acid gas. It was thereby possible without general anæsthesia thoroughly to freeze small foci in a few seconds and during the anæsthesia energetically to cauterise them. I usually repeated the whole process two or three times at one sitting. Four or five sittings in two months seemed to me sufficient to cure a fairly deep-seated process. In most cases the pain following the treatment was slight but in a few cases it was very considerable. For after-treatment I used poultices, powders, or pastes. The results appear, so far as can be judged from the relatively short time of observation, to be very favourable. My experience extends over cases of lupus vulgaris, tuberculosis cutis verrucosa, lupus erythematosus, ulcus cruris, primary syphilis, psoriasis, and sycosis vulgaris. The hard sores, which were all ulcerated, healed over in a few days after one application of the treatment by freezing and hydrochloric acid. A specific treatment for all cases has not yet been introduced. I had less success in two cases of psoriasis in which after disappearance of the reaction a fresh outbreak of the disease occurred. Ulcers of the leg, on the contrary, were very favourably influenced. An astonishingly rapid diminution in size and epithelialisation of the sores occurred. In about ten days they were completely healed. In lupus erythematosus, three cases of which I treated, the same favourable result with healing occurred as by simple freezing. The latter method appears to me preferable considering the superficial nature of that disease. The real field for Dreuw's method, if necessary with my modification with carbonic acid gas, is in tuberculous skin affections, which cannot be conveniently treated by Finsen light, Roentgen rays, or radium emanations. I had very good success in lupus vulgaris. As mentioned above, three months after the treatment by the modified method the foci showed on microscopic examination pure scar tissue. (Then follow notes of seven cases of lupus vulgaris, in all of which Juliusberg saw a very favourable influence on the disease.) Putting all my experiences together I am brought to the conclusion that the treatment by freezing has chiefly a destructive and caustic effect. This effect consists in the simple freezing method in a superficial necrosis and in the freezing and cauterisation in a deep necrosis of the tissue. Whether the marked serous transudation and leucocytosis have a good influence on the disease or not I cannot decide. At any rate, it seems to me that the chief use of the freezing method alone is in lupus erythematosus and of Dreuw's method in lupus vulgaris and carcinoma.

Rohden (Bad Lippspringe) describes the same good results in No. 21 of the *Deutsche Medicinalzeitung*, 1905. He says :—

> After many fruitless attempts and long treatment with Finsen light and x rays, in my experience of different caustics, besides the general and surgical treatment, I would recommend the ethyl chloride and hydrochloric acid method of Dreuw as surest and quickest. It gives lasting results and stands far above the Finsen light and the Roentgen rays in rapidity and simplicity. It can be carried out by any practitioner. Most cases which are represented as cured by Finsen light are not really cured, if one applies in the diagnosis the diascope or the phaneroscopic light method of Oscar Liebreich. The still unhealed lupus remains visible as yellow masses when the scar is pressed away by the glass.

As is shown by the foregoing the treatment of lupus by freezing and hydrochloric acid gives relatively good results and has the advantage of being very simple and inexpensive. It can therefore be applied by any practitioner. Even long-standing cases give in a relatively short time good cosmetic results. The method can also be applied with advantage in all other ulcerating processes in the skin, such as ulcers of the leg, venereal soft sore, primary syphilis, &c. No definite opinion, of course, can yet be formed as to the permanency of the results obtained because for that purpose years of observation are necessary.

To summarise once more the advantages of the *method* recommended by me, they are as follows : 1. The method is simple, cheap, rapidly effective, and gives good cosmetic results. 2. It can be carried out at home without hospital treatment, and that is especially important for patients of limited means. 3. Complicated apparatus is not necessary, therefore the method can be applied by any practitioner. 4. The method can be applied in all forms of *lupus* and in all situations, with the exception perhaps of the eye. Favourable results are obtained by repeated cauterisation, especially in lupus of the nasal cavity. 5. As a preliminary treatment for later Finsen treatment one gains time and gets favourable results.

Hamburg.

VACCINATION FEES.—The Loughborough (Leicestershire) board of guardians have fixed the following fees for public vaccinators : 4*s*. for each successful vaccination performed at the home of a person living in the same parish as the public vaccinator ; 6*s*. for each case of successful vaccination performed at the home of a person living in a parish in the public vaccinator's district other than the one in which he resides.

A CASE OF ACUTE LEAD ENCEPHALOPATHY FOLLOWING THE USE OF (?) DIACHYLON PILLS AS AN ABORTIFACIENT.

BY HOWARD F. WARNER, M.B., B.S. LOND.,
HOUSE PHYSICIAN AT THE LONDON HOSPITAL.

THE patient, a well-developed and previously healthy woman, aged 33 years, gave the following history. She was married and had had five children and two miscarriages ; she had done nothing to procure these miscarriages and could assign no reason for them. The youngest child was 13 months old, and she had again become pregnant lately. After from six to eight weeks' amenorrhœa, however, she consulted a female friend who gave her three distinct kinds of pills with directions to take one pill of each kind every morning and night. One of the varieties, she was told, was pennyroyal and the nature of the others she does not know, but in view of subsequent events there can be no doubt that one or both of the remaining varieties contained lead in some form, probably diachylon. She took these pills as advised at the rate of six a day for four or five days only without any appreciable effect and then a sudden accident occurred to one of the children ; she was very much frightened and ran for a medical man as fast as she could and almost immediately after this she had pains in the back and in the abdomen and began to lose blood copiously. .She kept about, however, for a fortnight, although losing continually, and at the end of that time had to go to bed owing to the miscarriage coming on. The miscarriage was attended by a medical man and everything went well. She was kept in bed for four or five weeks owing to anæmia and pains in her back and limbs. All this time she was quite clear mentally so far as can be found out.

The patient was then admitted to the London Hospital and the condition was as follows. The heart and lungs were clear. There was very marked anæmia but no paresis anywhere. Knee-jerks were present and were normal. There was no ankle clonus or Babinski's sign. She complained of pain in the back and limbs and colicky pain in the abdomen, and there was a fine tremor of the hands. The speech was very defective and the memory was much affected. Constipation was a very marked feature, and to clear up the difficulties of the case a *black* line nearly a quarter of an inch wide was found on the gums at the base of the teeth. This line was so extraordinarily wide and black that one hesitated to make the diagnosis of lead poisoning, but in some places, and especially along the margin of the line, the more typical blue character was seen. Mental symptoms rapidly developed after admission and in some respects closely resembled those of delirium tremens. The patient had delusions that people were talking about her and construed objects about the ward, of an inanimate, nature into people and animals. For a time she employed herself busily in trying to catch imaginary fleas and such things, but was never violent. Hallucinations soon came on also and she fancied that she saw animals, chiefly dogs, moving horizontally in front of her. A red man was also supposed to be in constant attendance. She became very restless, especially at night, tried to get out of bed, and would hold long "telephone" conversations in which the sequence of her remarks was quite lucid, but, of course, only her side of the conversation was heard and one was left to conjecture with whom she thought she was conversing. This condition continued for about ten days, during which time she was being vigorously treated with the sulphates of magnesium and sodium and was having trional (20 grains) and veronal (ten grains) at night to promote sleep. Sulphonal (20 grains) was also tried but on the whole the best results were obtained from the former mixture.

Towards the end of this period the patient was quite lucid in the day-time and henceforth her mental condition improved rapidly at night as well as day. Natural sleep was obtained and the bowels at last became free. The very marked anæmia reacted well to the treatment of gradually increasing doses of Blaud's pills and iodide of potassium was now added to her mixture of sulphates to eradicate the remainder of the lead. The line upon the gums diminished very rapidly and in a fortnight had all the appearances of the typical lead line ; it became much narrower and definitely blue and dotted in character, and now (28 days after admission) she is up and about with the anæmia rapidly complete its development in the mosquito. Thus the subjects could infect the anopheles wherever they might go. Among the Americans a large number of latent malarial infections occurred as complications of other diseases. These cases amounted to 106 and the original diagnoses included all forms of disease. Among the more frequent were chronic diarrhœa, chronic dysentery, amœbic dysentery, pulmonary tuberculosis, and chronic gastritis. In nearly all cases treatment with quinine by removing the malarial infection produced marked improvement. The cases of non-amœbic dysentery and diarrhœa raise the moot question whether there is a form of dysentery due to localisation of the malarial plasmodium in the capillaries of the intestine. The existence of latent malaria in a large proportion of native children who live in malarious districts has been shown by many observers. Koch found malarial parasites in the blood of 100 per cent. of native children in West Africa. As the children grow up the infection seems to disappear. Dr. Craig found malarial parasites in the blood of 51 per cent. of the Philippinos of a malarious locality. The æstivo-autumnal parasite predominated but all forms were represented. The adult Philippinos appeared to be infected much more frequently than the natives of Africa or India. Another form of latent malaria may exist in which no parasites are present in the peripheral blood. The disease then can be recognised only by splenic puncture or on necropsy. Dr. Craig has observed seven such cases in which death was due to some other disease and malaria was not suspected and was discovered on microscopic examination of the viscera. The spleen was considerably enlarged and its sinuses were congested and pigmented and contained numerous infected cells and pigmented leucocytes.

THE HEALTH OF HUDDERSFIELD.

THE county borough of Huddersfield has in recent years become famous among English municipalities by reason of the public spirit shown by the corporation in its efforts to improve the health of the people, and especially to reduce the formerly excessive infantile mortality. We have lately received the report of Dr. S. G. Moore, the medical officer of health, which deals with the mortality of that town in the first quarter of the year 1907. We direct attention to this report because of some remarks which it contains on the calculation of local rates of birth and of mortality. Dr. Moore is evidently dissatisfied with the national method of estimating populations, presumably because Huddersfield is thereby shown to possess a declining population. He points out that there is no ground for the assumption, on the one hand, that the rate of increase prevailing in the recent intercensal period changed abruptly at the time of the census, or, on the other hand, that the rate of decrease in that intercensal period must continue. Therefore he argues that in estimating local populations it is justifiable to take into account "the increase of inhabited houses, of scholars in attendance at schools, &c., as well as of the excess of births over deaths." These corrections Dr. Moore appears to have applied to the population of Huddersfield and thus to have arrived at the conclusion that instead of the decrease estimated by the national method the population of that town has increased since the last census by some 5000 people. Dr. Moore properly recognises that in estimating populations for his periodical returns the Registrar-General must employ a system which shall be generally applicable. Having no official knowledge of local conditions he has no choice but to follow this course. Upon this point, however, we may remark that it is for this reason amongst others that medical officers of health are expected to calculate rates of birth and death for their several districts, which shall be duly corrected according to local requirements. And, further, we believe that in at any rate one important instance the Registrar-General some years ago consented to revise his estimate of a population on his being supplied with satisfactory evidence derived from the local rate-books. We have no space here to discuss the difficult question of population estimates, but we entertain considerable doubt of the expediency of publishing death-rates for small populations and for short periods of time. Estimates of population on the national method for the whole country or even for large sections of the population have generally proved fairly trustworthy. But when, as in the case of Huddersfield, rates are published not only for quarterly periods but for separate diseases and for areas containing not more than two or three thousand inhabitants, the result is almost certain to be misleading.

DISLOCATION OF THE UPPER END OF THE FIBULA.

THIS is certainly one of the rarer dislocations, only some 25 cases being discoverable in surgical literature. An instance has been recorded by Dr. Frank B. Golley of Milwaukee in the June number of the *American Journal of Surgery*. A man, weighing about 13 stones, slipped and fell with his left leg and foot directly under him, and at the same time he heard something snap. When seen two hours later the chief sign visible was swelling over the ankle and the lower third of the left leg. No fracture could be found, but the external lateral ligament of the ankle was torn. Next day the patient complained of a grating or grinding sensation in the calf of the leg when the foot was flexed or extended. Dr. Golley then discovered a displacement outwards and forwards of the upper end of the fibula; it was especially noticeable when the foot was flexed or extended. The dislocation was easily reduced and a plaster-of-Paris bandage was applied. When the splint was removed three weeks later the displacement did not recur, but the ankle was stiff and lame for a month longer. Very rarely indeed this displacement may be the result of direct violence. In most cases it appears to be due to slipping or falling, the violent contraction of the muscles in front and at the outer side of the fibula, to check the fall, producing the displacement. In some cases, as in that above detailed, the leg and foot are forcibly twisted under the body, the foot being in a position of dorsal extension. In this way also severe traction would be made on the upper end of the fibula. If kept in position for three or four weeks there seems to be no tendency to recurrence.

THE LONDON COUNTY COUNCIL AND THE *MILK-SUPPLY*.

AT the weekly meeting of the London County Council on July 9th a report of the public health committee was presented dealing with certain proposals for legislation in the session of 1908. In this report the committee recognised that the most urgent need for legislation on public health matters was that of securing to the inhabitants of London a pure and uncontaminated milk-supply. There were clauses in the Council's General Powers Bill of 1907 enabling the Council to detect and to stop the supply within the county of tuberculous milk, and it was proposed that the Council should seek authority to deal with milk which at the time of entry into London was contaminated with dirt and filth. To that end the medical officer would have power to take samples of milk at railway stations and elsewhere and on ascertaining that such milk was tuberculous to inspect the farm from which the supply was derived. The supply would be stopped if it was proved that the cows were affected with hydrogen and *vice versâ*, and by exploding the mixtures and measuring the residual gas the percentage of reverse current can be calculated. By this method I found on using an x ray tube with an equivalent spark-gap of three centimetres and using no valve tube that 15 per cent. of reverse current was passing. And, on the other hand, by using an efficient valve tube I found that all the reverse current had been suppressed.

New Cavendish-street, W.

THE PROPHYLACTIC USE OF ANTITOXIN IN EPIDEMIC DIPHTHERIA.

BY EVERITT E. NORTON, M.R.C.S. ENG., D.P.H., &c.,
MEDICAL SUPERINTENDENT OF THE ISLEWORTH INFIRMARY.

EARLY in the present year diphtheria appeared in epidemic form at the Percy House (Brentford Union) Schools, which are under the management of the Poor-law guardians and are situated at Isleworth. There also, upon adjoining sites, are the infirmary and workhouse. The schools are residential, consist of various buildings, and accommodate about 300 children. Communication between the children of both sexes and different ages is in the class-rooms, at meal-times and otherwise, free; the older children walk out in small parties under certain restrictions; and the majority of the children are periodically visited by relatives or friends. Admissions and discharges are frequent, all children admitted or readmitted spending (in batches) a probationary period in isolation before mixing with others or attending classes. The schools are often full: thus in November, 1906, they contained 277 children and by the end of December the number had reached 309. Sick children are treated in the separate infirmary.

Before Christmas the fact had been noted that cases of septic sore-throat and follicular tonsillitis were occurring with a frequency somewhat unusual. During Christmas-time and the few days following the weather was inclement, and necessarily the children were much herded together in crowded, and consequently dusty, day-rooms, the hours spent under these conditions being prolonged by the fact that educational work, which is carried on in a separate building, was suspended. On Sunday, Jan. 6th, 1907, two children who, having sore-throat, had been transferred to the infirmary for observation and treatment were found to be suffering from diphtheria. A rigorous examination of all the school-children revealed suspicious conditions in the throats of a considerable number, and by the end of a week (Jan. 12th) 20 cases of diphtheria had been notified. It was found from the first to be necessary that the throat of every child in the schools should be daily inspected. All children found to be, or suspected of being, infected were isolated. Antitoxin treatment was at once commenced and free use was made of bacteriological examination of swabbings as an aid in diagnosis. The usual means of disinfection, &c., were stringently adopted with a view to limiting the risk of infection. Arrangements were completed whereby the majority of the children affected were transferred from the infirmary to the local (Mogden) isolation hospital and to the isolation hospitals at Acton and Ealing. These methods were steadily persevered in, but nevertheless cases continued to arise, the numbers notified during the weeks ended Jan. 19th, Jan. 26th, Feb. 2nd, and Feb. 9th being respectively 17, 7, 7, and 13, these, with two cases on Feb. 10th, making a total to that date of 66. The persistence of the outbreak and the fact that it affected all classes of children throughout the school proved only too clearly that a widespread infection existed. The board of guardians kindly gave me the opportunity of consultation (on Sunday, Feb. 10th) with Dr. R. Tanner Hewlett, and with his concurrence the use of antitoxin as a prophylactic measure was decided upon. The number of children in the schools was at this time 251. Swabbings from the throats of all were taken and were examined by Mr. E. C. Bousfield, of the Camberwell Research Laboratories. The 16 children from whose throats the specific bacillus or even a suspicious culture had been obtained after cultivation were isolated and were put under treatment with a view to freeing the throats from infection. On either Feb. 11th or 13th antitoxic serum was administered to every child, it being inconvenient to deal with all upon one day. The dosage was so arranged that the 16 children isolated received each 1000 units and all other children, as well as several members of the adult staff, each 500 units irrespectively of age. These quantities were, I believe, somewhat larger than have usually been adopted for protective purposes. It was thought, however, that, having in view the rarity of ill-effects from the use of serum injections as now prepared and administered, the degree of protection to be afforded should not be minimised by any diffidence. The children were still daily examined and carefully watched. A further case of diphtheria arose on Feb. 21st, another on the 27th, and two on March 2nd.

A second antitoxin injection was administered throughout the school on March 6th and 8th, the doses being similar to those previously given. No further cases occurred until April 9th when there was one. On April 12th there was another. Two more appeared on May 10th. With those cases the epidemic ended. Eight cases of diphtheria (all showing definite signs and all proved bacteriologically) arose, therefore, in different parts of the schools in children who had received the antitoxin treatment, two of these occurring more than two months after the second injection.

With regard to the causation of the outbreak there can be no doubt that diphtheria infection was carried into the schools at a time when conditions were favourable for its development. The arrangements under which the admission of children takes place practically preclude the possibility of a case of active diphtheria being admitted, but no swabbings for bacteriological examination are taken from the throats of children upon admission or during the period of probation. I have remarked that the early diagnosis of cases was only attained by daily inspection of all the children's throats. At the very commencement of the epidemic it was noticed that it was exceedingly uncommon for the diphtheritic children to make any complaint whatever or to show any symptoms of illness, so that in the great majority of the cases the presence of disease was first detected in the course of the daily examinations. Constitutional symptoms during the period of "invasion" were almost invariably absent and appeared only if, and when, absorption from the throat lesion had commenced.

The results of the daily inspection were very interesting. Getting, as one did, to "know by sight" many abnormal throats, surprising degrees of variation from week to week in their characteristics were not infrequently found. The presence of enlargement of the tonsils, of tonsils with deep crypts, of chronic pharyngitis, or of adenoid growths, did not appear to increase the susceptibility to diphtheritic infection. Some of such conditions, however, and especially the deep tonsillar crypts, seemed to favour the obstinate harbouring of the Klebs-Löffler and Hoffmann's bacilli and of other organisms. As a means of selecting children as especially liable to, or as being in the "incubation period" of, diphtheria naked-eye inspection proved utterly futile. I myself upon one occasion selected some 20 children as having absolutely healthy throats so far as could be observed; within 24 hours two of these had developed patches of membranous deposit upon the tonsils.

The method of daily inspection for the purpose of selecting cases for further examination was necessarily rapid. The children were easily taught to come up in turn each bringing a spoon, the handle of which was used as a tongue depressor. The spoons were thrown as used into pails in which they were subsequently boiled.

The ages of the 74 children who suffered from diphtheria were as follows: 5 were three years of age, 8 four years, 8 five years, 9 six years, 13 were from seven to nine years, 12 from ten to 12 years, and 19 from 13 to 15 years. The cases were usually treated in the first instance in the infirmary and seven remained there throughout. 20 were transferred to Mogden isolation hospital, 34 to Acton isolation hospital, and 13 to Ealing isolation hospital, where they were under the care of Mr. Herbert R. Power, Mr. D. J. Thomas, and Mr. Lewis D. Brown respectively, to all of whom I am indebted both for the interest which they took in our little patients and for the information with which they have kindly supplied me. The cases proved generally mild, and I attribute their favourable course partly to the fact that few young infants were included but chiefly to early diagnosis and prompt commencement of antitoxin treatment. The throat was free from membrane in many instances in 24 or 36 hours, and Mr. Thomas remarks that "most of the children were up and about at the end of the second week, an event very rare" in the cases admitted under his care.

to be slightly congested and in a position of extreme adduction, the patient breathing practically through the small aperture between the arytenoids or the "transverse triangle." That this adduction is not the result of paralysis of the abductors is proved by the facts that during laryngoscopic observation a momentary abduction of one or other cord can be seen from time to time and that after the cessation of the attack laryngeal movements appear to be absolutely natural. If laryngoscopic observation were at all prolonged the dyspnœa was much aggravated. Treatment by cocainisation, by narcotics, and by the passage of laryngeal bougies all proved unavailing. No other sign of disease was discovered and there was no indication that the condition was of hysterical nature. Dr. Hajek discusses the nature of his case and makes the suggestion that it may be an atypical form of tetany on the following grounds: the patient is a shoemaker, a trade which affords a not inconsiderable percentage of cases of that disease; cases of tetany commonly commence in the month of February; and in children, at any rate, the association between laryngeal spasm and tetany is well recognised. On the other hand, the dyspnœa was constant instead of intermittent, no trace of spasm in any other muscle was observed, while Trousseau's sign and the over excitability of the nerves (Erb's sign) were both wanting, the only other condition suggesting tetany being that the "facial phenomenon" was very marked. In discussing the possibility of an association between these attacks and the degeneration and extirpation of the thyroid body Dr. Hajek comes to the conclusion that it is improbable, since one attack began before the operation was performed, while after it there was an interval of two years free from dyspnœa. The case is an obscure one and its actual nature is admittedly doubtful, but in support of Dr. Hajek's suggestion it is interesting to recall that tetany is very common in Vienna and may occur in epidemics, especially during March and April, and that of 399 cases collected by Frankl-Hochwart 174 occurred in shoemakers.

"PREVENTIVE MEDICINE THE MEDICINE OF THE FUTURE."

AT the Congress of the Royal Institute of Public Health which was held at Douglas (Isle of Man) at the beginning of this month, Sir James Barr delivered a presidential address in the section of preventive medicine, which in its vigour of expression and felicity of phrase was well worthy of its distinguished author. He took for his text "Preventive Medicine the Medicine of the Future," and preached a crusading sermon against the *laissez-faire* attitude with which too many people are content to contemplate a vast amount of preventable disease and self-inflicted national degeneracy, and he did not spare that curious perversion of "Religion" that attributes to the will of God the results of our own national hygienic and genetical shortcomings. He began by remarking that in interesting himself in preventive medicine he was not opposing his professional interests, for "as long as people are alive there is a chance of making something out of them, but once they are dead the interest of the medical man ceases, except from a pathological standpoint, or in the aggregate for statistical information." He then proceeded to unfold his main contention that the reason why the successes of sanitarians have been limited is because they have devoted so much attention to the prevention of zymotic disease and the preservation of life rather than the improvement of health. If medical men would deal with physiological conditions as well as pathological, and tell patients how to keep well and not merely how to get well, they would get more patients. This is a very pretty theory, but we are not able to endorse it fully. If there were a real demand for information as to the rules of health on the part of a large number of people we may be sure that our profession would be only too pleased to supply them; the trouble is to get even those who are ill to follow the dictates of reasonable authority as to their mode of life unless they be actually suffering some pain or other subjective reminder of their condition. If, however, the profession as a whole would more firmly impress the vital importance of prophylactic personal hygiene upon all and sundry as readily as it has, since the decline of Greek medicine, dealt out drugs to them, the public demand for advice on the best manner of living in order to prevent disease might become as general as has the clamour for physic to cure it. Sir James Barr devoted some attention to political matters, especially urging that before granting pensions to old people it is the duty of the nation to provide for the adequate nutrition and hygiene of its nursing mothers and young children, and to see that its school children are properly fed before any attempt is made to teach them, whilst it might well leave to individuals the care of their own old people. He quoted Lord Beaconsfield to the effect that "The public health is the foundation on which repose the happiness of the people and the power of a country. The care of the public health is the first duty of a statesman." He considered that if the nation will only do its duty in this matter there will speedily follow a check to the diminution of the birth-rate and, what is of more importance, a marked decline in the infantile death-rate. We need not enter into his discussion of the latter subject as it has been so often before our readers, although it cannot be too often restated to the public with such force as Sir James Barr knows how to infuse into his utterances. He paid a handsome tribute to the *personnel* of the navy and the army as the flower of English manhood and the hope of salvation of the country and extolled the military training as the best means of insuring national health and physique. Passing to the question of physical deterioration he favourably regarded Dr. Rentoul's drastic proposals to prevent the propagation of the race by the unfit and he expresses his view that heredity has much more to do with the welfare of the nation than those who so strongly proclaim the all-important influence of environment are disposed to allow; he agrees, in fact, with the transatlantic counsel that a man cannot be too careful in the selection of his parents. He is much concerned at the deafness of our legislators to the report of the Committee on Physical Deterioration, to the opinions of which he gives his full support. He is able to find some consolation in the national outlook on the distaff side and remarks, "I have great faith in the British women, the potential mothers of the next generation. They do not show so much deterioration, except in the very lowest strata, as the men, and in the upper and middle classes the girls of to-day will bear a very favourable comparison to their mothers and grandmothers." The last half of the address consisted of an examination of the increase or decrease that has taken place of recent years in the death-rate from various diseases. After giving credit to sanitary science for the decline in the ravages of tuberculosis and many of the specific infectious disorders he called attention to the fact that there has not been a corresponding diminution in deaths from those that more especially affect children, but his chief indictment was against the apathy that exists concerning the enormous yearly loss of life from pneumonia which with the observance of proper caution might be a much more preventable disease than it is considered to be. He dwelt also on the wide scope for preventive medicine in guarding against diseases of the heart, kidneys, and blood-vessels which are on the increase owing "no doubt largely to greater wear and tear, more worry and anxiety in life." It is in this sphere undoubtedly that the preventive activities of the general practitioner should find their scope and we consider that Sir James Barr has done of twice the length. I have also found a rubber ear syringe (*one in which the ball and nozzle are composed of black* rubber) to be most useful for washing the glass tubes, since one can affix the compressed ball to the tube and allow it to suck up water or alcohol for cleaning, and thereafter by compressing it the fluid is entirely discharged.

Edinburgh.

NOTE ON BREAD AS A SOURCE OF URIC ACID.

BY ROBERT SAUNDBY, M.D. EDIN., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE AT THE UNIVERSITY OF BIRMINGHAM.

IN Professor Armand Gautier's "Diet and Dietetics," of which there is a not very satisfactory translation published by Messrs. Constable and Co., he draws attention to a fact which is little known in this country—that bread may be a source of uric acid by setting free an excess of phosphoric acid (0·239 gramme of phosphoric acid per 100 grammes of new bread), an acid that does not find any base which can neutralise it.

In the early part of this year a boy, aged nine years, was admitted into the General Hospital, Birmingham, under my care for acute nephritis. There was swelling of his face and legs; his urine was scanty and high coloured and contained blood, albumin, and epithelial and granular casts. His body was covered with numerous scabs and scratches and little raw red spots, *and it seemed to me* probable that the nephritis was *caused by the absorption* of some irritating substance which had been applied to his skin, although we were never able to obtain absolute proof of this.

The patient was treated at first by being put to bed in blankets and given imperial drink; his bowels were opened by scammony resin, and boric acid *fomentations* were applied to the sores on his legs. A week later the whole of his *body* was *anointed daily* with the following lotion: *Sodium* biboras, 3 *drachms*; oleum *olivæ*, 4 *ounces*; aq. rosarum to 8 ounces. The skin soon became perfectly *healthy*. The blood and casts *disappeared* from the urine although there was *occasionally* a *haze* of albumin, but there was a very copious *deposit of uric acid* which was first noticed on Feb. 12th, about a month *after* his *admission*, although he was on a diet containing only milk, bread, butter, light *puddings*, cocoa, and fish. The uric acid persisted in spite of large *doses of citrate of lithium* up to 15 grains at bedtime. The *cocoa and fish were stopped* on Feb. 20th; on the 22nd he was given *urotropin*, five grains at bedtime, and this was *increased* to twice and three times a day without effect. On March 3rd lithia was *again tried*, 15 grains first at bedtime, then twice a day, then three times a day, *and on the* 18th five grains of urotropin were added to each dose of the mixture, entirely without effect. *From* March 19th to April 8th solurol up *to four tablets daily was given, also without* apparent influence. On April 26th *potatoes* were substituted for bread, which was removed from his diet, and during the *time that he took no* bread no uric acid appeared. On the 30th he was allowed two ounces of toast with each meal, with the result that the uric acid *reappeared occasionally* so that the quantity of toast was reduced to one ounce.

As the boy was in other respects well *and* had been in the hospital nearly three months we were obliged to let him go and the observation was discontinued, *but so far as* it went it supports Professor Gautier's *opinion*. As the influence of bread as a possible cause of the deposit of uric acid is not generally admitted I *have thought* it worth while to publish this brief note to call attention to it.

Birmingham.

NOTE ON THE SYMPTOMS AND TREATMENT OF HAY FEVER.

BY JOSEPH A. W. PEREIRA, M.D. BRUX., L.R.C.P. LOND., M.R.C.S. ENG.,

MEDICAL OFFICER TO THE EXETER CITY WORKHOUSE.

HAY fever, or hay asthma, is an extremely distressing disease. It is also a very prevalent one. Unfortunately the treatment is unsatisfactory, so much so that Watson Williams, reviewing it for the *Medical Annual* of 1905 (p. 312), says: "The prevalence of this troublesome complaint demands full *trial of any method which is likely to be* successful." I believe this failure in treatment is to be explained on the ground that the disease is looked upon too exclusively as a disease of the nose and upper respiratory passages, whilst the affection of the conjunctiva is overlooked. Yet I believe the eye affection is at the root of the disease and precedes by several hours the irritation in the nares. Before *mentioning* the treatment which I have found most satisfactory I shall briefly enumerate the symptoms in the order in which they occur.

On the first bright warm June day the disease manifests itself by a feeling of itchiness at each inner canthus. On examining *the eyes a slight hyperæmia* of the bulbar conjunctiva is noticed. This gradually increases and causes photophobia *and sneezing when the eyes* are turned towards a bright light. There is no secretion from the *conjunctiva*, although there is a copious flow of tears. The hyperæmia assumes a distinctly conical shape, with the apex touching the cornea, the base being towards the nose. The intense irritation in the eyes *forms* one of the most distressing features of the disease. As the eye affection grows worse the frequency *of sneezing increases until scarcely* an hour of the day passes without violent paroxysms. A feeling of intense irritation in the mucous membrane of both anterior and posterior *nares occurs* and a *watery secretion runs* from the nose. The sneezing causes intense occipital headache. The disease is now at its worst. Great depression and malaise ensue. The general health is so impaired that the skin breaks *out into profuse perspiration after* each fit of sneezing. The disease lasts for about three weeks.

The points which I wish *to emphasise are* these: 1. That the disease begins as a hyperæmia of the conjunctiva and that the other symptoms are mostly reflex. 2. That the eye affection known as *pterygium is merely an exaggerated* condition of the same affection of the eye made permanent in hot climates "where the air is filled with *fine sand or other* minute particles."[1] 3. That sufferers from pterygium are invariably great sufferers from hay *fever*.

The eye being the chief seat of the disease one is not surprised that the profession, led by such popular works as Osler's "Principles and Practice of Medicine" *or* Whitla's "Dictionary of Treatment," which describe the disease as entirely an affection of *the nasal mucous membrane*, has gone astray on the question of treatment. The disease lies quite as much within the province of the ophthalmic surgeon. On consulting Swanzy's "*Diseases of the Eye*" (*second edition*, p. 83) I find that he recommends dark glasses for protection from the light, weak astringent collyria, &c. The fact is, the eye wants protection, not from the light, but from the dust. Intolerance of light is only secondary to the irritation caused by the dust. *This* protection is afforded quite as well by colourless *glasses as by* tinted ones and they are not so unsightly. The colourless glasses should be fitted into frames of the pince-nez variety, *for the reason* that they best protect the inner canthi, and also for the physiological reason that pinching the root of the nose often stops a sneeze. Protecting the eyes does not *cure the disease* but all the symptoms are so effectually relieved that hay fever becomes a comparatively trivial affection which scarcely *interferes with the routine* of life.

Exeter.

A CASE OF THE APPENDIX IN A FEMORAL HERNIA, THE PATIENT ALSO EXHIBITING A CURIOUS CYANOTIC CONDITION.

BY F. CARMINOW DOBLE, M.R.C.S. ENG., L.R.C.P. LOND.,

HOUSE SURGEON AT THE GREAT NORTHERN CENTRAL HOSPITAL.

AN *unmarried woman*, aged 44 years, was admitted into the Great Northern Central Hospital on May 21st with a double hernia. An *operation* was performed by Mr. E. C. Stabb on May 22nd. On the right side an *oblique* incision was made over the lump and a *tense swelling* was *discovered* which *felt* like an enlarged lymphatic gland. This *after* a little dissection *proved to be* a hydrocele in the distal end of the *femoral sac*. *The proximal* end of the sac was found coming through the lower end of the *crural canal*. On opening the sac the *appendix was found*, the tip *being* very adherent to it. The appendix was removed, without enlarging the opening, by *the cuff method*, the stump being buried by Lembert *sutures*.

---

[1] Swanzy's Handbook of Diseases of the Eye, second edition, p. 169.

of their daily life, and 10*s.* could not be more profitably invested. Subscriptions and donations, however small, towards this object will be welcomed by the secretary of the Children's Fresh Air Mission, St. Peter's Schools, Onslow-street, Clerkenwell-road, London, E.C. Another appeal for help comes from the Boys' Brigade Seaside Camp, of which the secretary is Mr. R. S. Peacock, 34, Paternoster-row, London, E.C. "Last summer," the President writes, "2768 London boys out of a membership of 7000 were able to taste the delights of a week or ten days under canvas and a larger number still are hoping to be present this year. While the boys themselves, by saving up their spare pence during the winter months, contribute over one-half the cost of the camps, a large sum is needed to supplement their payments. The cost per boy is about 15*s.* Thus every pound contributed will enable three boys, who would otherwise perforce spend such holiday as they receive in listless idleness in the hot and arid streets of the metropolis, to join with their comrades in the joys of a week by the sea." The advantages of a holiday of this kind are too obvious to need any comment and we trust the brigade will receive the support which it certainly deserves.

A CASE OF CEREBRO-SPINAL MENINGITIS POSSESSING MEDICO-LEGAL INTEREST.

EPIDEMIC cerebro-spinal meningitis is fortunately somewhat rare in London, only seven deaths from this very fatal disease having occurred within the metropolitan area during the month of May. The most recent case to which public attention has been directed presents some remarkable features. The patient was a costermonger, aged 28 years, who was assaulted by roughs in Radnor-street, St. Luke's, on June 16th, and received lacerated wounds of his head and face, for which he was surgically treated. He was afterwards admitted to St. Bartholomew's Hospital with symptoms which, in conjunction with his other injuries, were supposed to indicate fracture of the skull. Death took place on June 27th but at the necropsy there was no evidence of fatal lesions due to the assault. A diplococcus was, however, discovered in the cerebral fluids or membranes and in the result the jury returned a verdict to the effect that death was caused by cerebro-spinal meningitis, or "spotted fever." One of the men who attacked the deceased received a sentence of two months' hard labour and no doubt his associates are relieved to find that a charge of manslaughter will not be preferred against them.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-sixth annual meeting of this association will be held on Thursday and Friday, July 25th and 26th, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. P. W. MacDonald. There will be a meeting of committees previously, on Wednesday afternoon. The council will meet at 9.30 A.M. on Thursday morning and the annual meeting will commence at 11 A.M. After the election of officers for the ensuing year, the adoption of reports, and other formal business has taken place in the morning the President will deliver his address in the afternoon and Dr. Charles C. Easterbrook will read a paper entitled "The Sanatorium Treatment of Active Insanity by Rest in Bed in the Open Air." In the evening the annual dinner will take place at the Whitehall Rooms, Hôtel Métropole, at 7.15 for 7.30 o'clock. Tickets £1 1*s.*, wines included. On Friday morning Dr. T. S. Clouston will introduce a discussion upon Psychiatry as a Part of Public Medicine; Dr. Albert Wilson will give a clinical demonstration and read a paper on the Psychology of Crime; and Dr. Henry Devine will read the notes of a case of katatonia in a congenital deaf-mute, illustrated with lantern slides. In the afternoon Dr. W. Ford Robertson and Dr. G. Douglas McRae will communicate "Observations on the Treatment of General Paralysis and Tabes Dorsalis by Vaccines and Antisera," and Dr. Lewis C. Bruce will read a paper entitled "Clinical Observations on Certain Cases of Mental Depression." Members are requested to notify their intention of dining to the honorary general secretary, Dr. C. Hubert Bond, at 11, Chandos-street, Cavendish-square, London, W.

WORKMEN'S COMPENSATION ACT, 1906.

THE Home Secretary has made the following regulations as to examinations of a workman by a medical practitioner provided and paid by the employer under the provisions of the First Schedule to the *Workmen's Compensation Act*, 1906:—

1. Where a workman has given notice of an accident or is in receipt of weekly payments under the Act, he shall not be required to submit himself, against his will, for examination by a medical practitioner provided by the employer except at reasonable hours.

2. A workman in receipt of weekly payments shall not be required, after a period of one month has elapsed from the date on which the first payment of compensation was made, or if the first payment is made in obedience to the award of a committee or arbitrator, from the date of the award, to submit himself, against his will, for examination by a medical practitioner provided by the employer except at the following intervals: Once a week during the second, and once a month during the third, fourth, fifth, and sixth months, after the date of the first payment or the award, as the case may be, and thereafter once in every two months.

Provided that where after the second month an application has been made to the county (in Scotland, the sheriff) court or to a committee for a review of the weekly payment, the workman may be required, pending and for the purposes of the settlement of the application, to submit himself to one additional examination.

The suggestions seem to us to be quite reasonable and satisfactory.

THE CHAIR OF PATHOLOGY, OXFORD.

THE electors have appointed Dr. George Dreyer to this newly founded and important chair at the University of Oxford. Dr. Dreyer is a lecturer on pathology in the University of Copenhagen, where he is chief assistant to Professor Salomonsen, and is well known for his able researches on bacteriology, pathological histology, and the complex problem of immunity. Those who were at the meeting of the pathological section of the British Medical Association at Oxford will remember the able part which he took in the discussion on immunity and will remember that he speaks English with great facility. Dr. Dreyer worked for some time with the late Sir John Burdon-Sanderson and is very well known to the younger Oxford men, a number of whom have carried on researches with him at Copenhagen. Dr. Dreyer is the son of Captain Dreyer of the Danish Navy and was born at Shanghai in 1873, and it is probable that his comparative youth, his other claims being very strong, helped to determine the issue of the election.

IN consequence of the death of Sir William Broadbent, senior consulting physician to St. Mary's Hospital, the presentation of prizes to the successful students of the medical school by Professor W. Osler, which had been arranged for Thursday, July 11th, was postponed.

THE distribution of prizes gained by the students and nursing probationers of the London Hospital and Medical College will be made by Mr. Hudson E. Kearley, M.P., on Wednesday, July 17th, at 3.30 P.M., in the library of the Medical College.

WE note with pleasure the grant of a *Civil List Pension* to Dr. Charles Creighton, the author of the "History of Epidemics in Britain."

A LOCAL Government Board inquiry was held at Bude on July 3rd into the application of the Stratton and Bude urban council to borrow £14,000 for sewage disposal.

the enormous amount of observation expended on their elucidation, there was still a marked absence of agreement on the subject. In answer to the statement that pregnancy and parturition were causal factors, it might be stated that the majority of cases occurred in nulliparous women and the extreme form of moveable kidney was met with chiefly in males. Mr. Thomson did not think that tight-lacing was a great factor in inducing the condition. Various other conditions usually described as causing renal displacement were discussed, and the overwhelming predominance of abnormal mobility on the right side could not be explained on other grounds than the presence of the liver and the difference in the position and attachment of the flexure of the colon on the two sides. The anatomical relations were discussed and it was shown that the transversalis fascia was split into two layers inclosing the kidney. These were united above and on either side but did not unite below. The kidney was anchored in this space with little to interfere with its displacement downwards and inwards. The fascia inclosing the space became in cases of moveable kidney comparable to the sac of a hernia. The influence of violence in producing the condition would not stand criticism in most cases. With regard to treatment it was only in a small proportion of cases in which there were symptoms directly referable to the renal displacement that operative treatment should be considered. While Mr. Thomson had obtained satisfactory results from one or another of the methods employed for fixing the kidney or its capsule by means of sutures, he had come to regard the procedure, which consisted in forming a shelf below the organ, as one to be preferred. The incision commenced at the tip of the twelfth rib and was continued downwards and forwards in the line of the external oblique; the fibres of the three layers of abdominal muscles were separated in the usual manner, the posterior layer of perirenal fascia divided, and the kidney exposed. Having removed the perirenal fat from the lower pole of the kidney, interrupted sutures were passed so as to bring together the parietal peritoneum and anterior layer of the perirenal fascia in front and the posterior layer of the perirenal fascia and lumbar aponeurosis behind. If the peritoneum was opened outside the line of the colon, the passing of the stitches through the peritoneum was more efficiently and more safely carried out.—Mr. J. M. COTTERILL said that up to the present no method of treatment could be considered entirely satisfactory when the patient was only kept on his back for three weeks after operation. No method was effectual so far as the mere stitching went. His own practice was to get rid of the perinephric fat from the outer and upper parts of the kidney and to fix the organ up and in the back part of its sac. In order to do this he stuffed the lower part of the cavity with a large pad of gauze. The essence of success, however, lay in keeping the pelvis well elevated, and if the patient were kept in bed for six weeks no relapses occurred.—Mr. H. J. STILES asked if it would not be wise to combine the two methods of stitching the upper part of the kidney and fixing it by a shelf below. He was far from satisfied that a correct solution of the cause of moveable kidney had been arrived at.—Dr. DAVID WATERSTON and Dr. H. M. CHURCH took part in the discussion.

Dr. FORD ROBERTSON and Dr. MCRAE made a communication on the Treatment of cases of General Paralysis and Tabes Dorsalis by Vaccines and Anti-sera. They stated that the investigations which had led them to employ specific vaccines and anti-sera in the treatment of these diseases had been the subject of several papers, the most recent of which had formed the basis of a discussion at a meeting of the Medico Psychological Association on May 16th last. They described the distinctive characters of the two types of diphtheroid bacilli that they had used in the preparation of the vaccines and anti-sera. Both micro-organisms showed a considerable degree of virulence to mice, and both had produced in rats fed with cultures a disease resembling general paralysis. They believed that these were not the only species of diphtheroid bacilli that were commonly concerned in the production of the toxæmia of general paralysis and tabes, but that, just as in the case of the pathogenic streptococci, numerous different but closely allied species were capable of exercising a similar pathogenic action. They described the methods which they had employed in vaccinating with killed cultures and the local and general effects produced in eight cases of general paralysis and one of tabes. In most of the cases there was distinct improvement in the patient's physical and mental condition, followed by relapse after several weeks. In one case of general paralysis the improvement had been very striking and had been maintained for a year, when the patient was removed from the asylum. The case of tabes had a special interest in respect of the facts that the bacillus used was one that was abundant in the patient's bladder and that on several occasions the subcutaneous injection of the killed cultures was followed in about 12 hours by a distinct attack of lightning pains. This patient had certainly improved. Dr. Ford Robertson and Dr. McRae explained that the vaccine treatment was temporarily abandoned a year ago when an anti-bacterial serum became ready for use. Their whole time had since been occupied in the preparation of this serum and in the study of its effects. The few observations which they made seemed to show that repeated vaccination with these cultures might prove a useful mode of treatment in cases of general paralysis and tabes. This opinion was supported by the results of the independent observations of O'Brien in America, who had recently reported that he had obtained considerable success with such methods in cases of general paralysis. They considered that three conditions would require to be fulfilled in the carrying out of this treatment—namely, (1) the bacillus ought to be one isolated from the patient; (2) there should be evidence that it is exercising a pathogenic action upon the patient; and (3) the injection should be carried out under the guidance of the leucocyte count or of the opsonic index. They next described their procedure in preparing anti-sera in the sheep. They had now 12 sheep immunised to various strains of virulent diphtheroid organisms isolated from cases of general paralysis and tabes. The serum was given generally in doses of 20 cubic centimetres hypodermically or by mouth. The local effects of hypodermic injections were, as a rule, trivial, but occasionally there was passing erythema and serum urticaria. The immediate general effects were chiefly drowsiness, diaphoresis, and malaise; many of the patients became confused, some were hilariously excited; the speech, gait, and coördination were for a time more impaired and tremors were increased. The temperature reaction was characteristic and, so far as their experience went, it was diagnostic. It consisted in a rise to about 100° F., or a higher level, when the serum was given hypodermically. This rise occurred within 12 hours and was over in 24 hours. Details of several cases were given. Altogether 26 cases of general paralysis and two of tabes had been treated. Out of 12 cases of general paralysis that had been under their own immediate supervision for over a period of three months ten had shown remarkable degrees of improvement. Out of five cases treated indirectly by them for a sufficiently long period to obtain therapeutic results three had improved. In one of the cases of tabes, which had been under treatment for about five months, the severity of the pains had greatly diminished, whilst the duration of the periods of remission had increased. The second case of tabes had been under treatment for only a few weeks, but already results of a similar nature were being obtained. Nine control cases had been subjected to the anti-sera, each on at least three occasions, two of them 11 and ten times respectively. In none of these did any specific reaction occur after mouth administration, and any rise of temperature subsequent to injection could readily be explained by other factors. Several cases of general paralysis had also been subjected to treatment with the serum of normal sheep and also with anti-streptococcic serum, in order to test the specific character of their anti-sera. In no case were these injections followed by any reaction similar to that which ensued upon injection of antiparalytic serum. They formulated the following five conclusions: (1) the anti-sera with which they had been working produced reactions that were diagnostic of general paralysis or tabes after three injections; (2) cases treated with these sera had in most instances shown improvement; (3) a polyvalent anti-serum was likely to be more efficacious than either the mono- or bivalent serum which they had hitherto used; (4) one of the chief obstacles in the way of obtaining a very potent serum had been the loss of virulence in the strains of the organisms used; and (5) there were grounds for believing that an antitoxic serum would be of use in these cases and this they now proposed to make and to test upon patients in conjunction with, or separately from, their anti-bacterial serum.

MIDDLESEX HOSPITAL CANCER RESEARCH LABORATORIES: SIXTH REPORT.

THE laboratories which have been established in connexion with the cancer wards of the Middlesex Hospital are carrying out many important investigations concerning malignant disease, and this, the sixth, report contains quite as much that is worthy of notice as any of its predecessors. While all the papers contained in it are valuable some of them are naturally of more interest than others. With the paper on the trypsin treatment of cancer we hope to deal next week.

Dr. Archibald Leitch has been working on the question of the presence of micrococci in tumours. Rapin in 1887 first described micrococci in carcinomata and Motz discovered them in sarcomata in 1894. In 1904 Doyen reported that a special micrococcus was to be found in tumours both malignant and simple. Metchnikoff has confirmed these observations and Dr. Leitch's paper is an account of the attempts which he has made to isolate this particular micro-organism from new growths. In all 33 tumours were examined; of these 15 were unulcerated mammary carcinomata; three were cases of carcinomata which were either ulcerated or which had been on an exposed surface; three specimens were sarcomata; four were simple tumours, two of them fibro-adenomata of the breast and two fibro-myomata of the uterus; and eight of the specimens were taken from animals, one being a breast carcinoma, two were tumours containing cartilage, one was an enlarged lymphatic gland, one a breaking-down granuloma, and three were transplanted tumours from mice. It will be seen that there was great variety in the tumours examined. Great care was taken that no infection of the tumours took place from without and culture tubes were inoculated. From these tubes a micro-organism was obtained, which was definitely a staphylococcus without any very special characters—at least, its characters are not sufficient to specify it. It was found in a very large proportion of the specimens examined, and except in the ulcerated or surface-exposed tumours it was a nearly pure growth. The real point of importance is that a coccus of certain characters is found in neoplasms. The question of the relation of this micrococcus to the new growth is entirely another matter. At present it can only be said that in a very large proportion of tumours, both innocent and malignant, a special micrococcus exists.

Dr. J. J. Douglas, working in the Middlesex Hospital Cancer Research Laboratory, showed three years ago that the blood of patients suffering from cancer has a lower specific gravity than the blood of normal individuals, the average difference being 0·007. Mr. C. W. Rowntree in the present report records some observations which he has made as to the difference of the specific gravity of the solid tissues in the bodies of cancerous patients and of those dying from other causes. The method employed was devised by Dr. W. S. Lazarus-Barlow. It consists in having layers of a watery solution of gum arabic with a little formalin to prevent the growth of moulds. The layers, which contain more or less gum, have different specific gravities and have very little tendency to mix, and to distinguish them alternate layers are stained with methylene blue. There is a difference of 0·002 in specific gravity between adjoining layers. A small piece of tissue is snipped off with sharp scissors, care being taken to bruise it as little as possible in order that the tissue fluids shall not be squeezed out. The piece of tissue is then placed in the uppermost layer of a series of gum solutions; it sinks rapidly at first and then more slowly until at last it comes to rest in the layer which has the same specific gravity as itself. The chief differences were found to exist in the case of spleen and voluntary muscle. Each of these tissues was found to have diminished about 0·003 in specific gravity. Mr. Rowntree comes to the conclusion that this reduction in specific gravity in cancerous cases depends not upon any specific change in the tissues themselves but upon the changes in the blood which have been shown to be present in carcinoma of all forms.

Dr. Victor Bonney, who is the Walter Emden Research Scholar, contributes a valuable paper on the connective tissues in squamous-cell carcinoma and in leukoplakia. He finds that in the earlier or more acute stages of leukoplakia there are large numbers of lymphocytes in the subepithelial tissue, especially at the tips of the interpapillary downgrowths of the epithelium, but their distribution is somewhat irregular. These lymphocytes invade the epithelium, intercalating themselves between the individual epithelial cells, especially in the Malpighian layer. In quiescent states the lymphocytes disappear. In squamous-cell carcinoma the lymphocyte is still more prominent, but its distribution is similar to that found in leukoplakia. Dr. Bonney does not think that these lymphocytes are derived from the pre-existing connective-tissue cells, as division by mitosis or amitosis is never to be observed in them. He considers that they are brought to the spot by the lymphatic capillaries. As to what happens to them he is in more doubt; certainly they take no part in the formation of the stroma of the growth. He thinks that the lymphocytes are pushed back by the advancing epithelial cells. In the acute stages of leukoplakia and in squamous-cell carcinoma Dr. Bonney finds plasma cells present in great numbers, mixed with the lymphocytes. The plasma cells proliferate, chiefly amitotically, but the proliferation is best seen at a little distance from the epithelial cells. He is unable to suggest any very likely source for the plasma cells, but he feels sure that a local proliferation is responsible for the great number present, for delicate processes unite them to other plasma cells and therefore it is very improbable that they have been brought to the affected spot. The plasma cells probably become fibrous tissue cells and the dense fibrous tissue is probably largely due to the deposition of collagenous material around a framework of elongated plasma cells and fibroglia fibres. Dr. Bonney thinks that the fixed connective-tissue cells play an unimportant part in the tissue reaction accompanying leukoplakia and squamous-cell carcinoma, though it is possible that they give rise to plasma cells. The other chief changes seen in the invaded tissues affect the fibrous tissue. There is a disappearance of much of the collagenous matrix; this rarefaction is mainly due to the plasma cells, which by their proliferation produce rifts in the homogeneous collagenous matrix. This occurs at some little distance in advance of the epithelial downgrowths. Both in leukoplakia and in squamous-cell carcinoma there is an early and permanent disappearance of the yellow elastic tissue. These histological results are of great importance and increase our knowledge greatly of the changes occurring in the tissues invaded by leukoplakia and by carcinoma.

Dr. Lazarus-Barlow has contributed a very elaborate paper on the Retardation of Electroscopic Leak by means of recognised radio-active and certain other substances which have been supposed to bear a causal relationship to definite varieties of cancer. The paper is based on an enormous number of experiments and we have only space for the chief conclusions. An aluminium disc which has been placed in proximity to a recognised radio-active substance has acquired a retarding action on the leak of an electroscope, and this is independent of the character of the electricity with which the gold leaves are charged. He has also shown that cholesterin, gall-stone, and paraffin wax have a similar effect, but pipe-clay accelerates the leak.

Dr. Lazarus-Barlow and Mr. Cecil R. C. Lyster have also made observations on electroscopic leak in the presence of aluminium and glass plates that have been exposed to x rays. They conclude that there is no alteration in the rate of leak.

We have given the substance of the chief papers in this report in order to show the importance of the investigations which are being carried out in these laboratories. The exact relation of many of these observations to the production or extension of cancer may not be obvious, but the more we learn about cancerous processes the more we are likely to become acquainted with the true etiology of malignant disease.

THE CUMBERLAND INFIRMARY.—The sixty-sixth annual report of the Cumberland Infirmary shows that that institution is in a prosperous condition, the debit balance on the general account having been reduced to £179, whilst the capital account received an addition in legacies during last year of £1624. 1127 in-patients and 2540 out-patients were treated; the cost per bed per day has been reduced from 3s. 3¾d. to 3s. 0½d. It is proposed to institute an ophthalmic department of the infirmary and two surgeons are to be appointed to it. The vacancy in the presidency of the infirmary caused by the death of the late Sir Wilfrid Lawson, Bart., has been filled by the election to the post of the Right Rev. the Lord Bishop of Carlisle.

r brackets or by new articles specially written. The terature lists have been omitted but a few references to nportant original papers remain.

In regard to the lexicographic part of the work, the choice f words made appears to have been comprehensive. The efinitions given are short and succinct but in most cases uite clear and sufficient; sometimes a second definition is iven in explanation of the first. A useful addition to the efinition of words is that, wherever possible, cross references are given to the various articles where further information is supplied in regard to the subject with which the articular word is employed. Occasionally such references ake the place of definition, which, in spite of the editor's laim that they are quite sufficient to indicate the meaning f the word, is irritating and likely to cause waste of time here a definition only is required, as may be seen in the nstances quoted by him—viz., Aglaukopsia is not defined—he reader is referred to Colour Vision (Green Blindness); nd Agaricus has simply attached to it the cross reference oxicology (Fungi), in both instances requiring reference to nother volume. It is only fair, however, to state that uch instances are rare and that in practically all cases the lefinitions given are sufficient. Although the words are lphabetically arranged there is an index at the end of the olume giving the words dealt with and the pages upon which they are described.

The second volume carries the subject matter of the "Encyclopedia and Dictionary of Medicine" from "Bread" o "Ear," and the features which characterise the first volume are maintained. In addition to the articles which appeared in "The Encyclopedia Medica" new contributions on such recent developments of medical diagnosis and treatment as cryoscopy, cytodiagnosis, and dechlorination have been added; and dermatitis traumatica et venenata in coal-miners is dealt with in a special contribution.

We have on previous occasions deprecated the plan of calling a disease after the observer who first described or minutely investigated it. The accumulation of such names has already become very confusing. Under the heading "Disease" in this volume will be found a list of nearly 100 maladies so distinguished with a brief definition attached to each. This will prove useful for reference and will aid in the recognition of the various morbid conditions. We may add that it is stated in the introduction that it is proposed to issue supplementary volumes as a Quinquennium of Medicine and Surgery after the completion of the present work in order to keep pace with the advance so constantly occurring.

Handbuch der Geburtshülfe (Handbook of Obstetrics). In three volumes. Edited by F. VON WINCKEL. Wiesbaden: J. F. Bergmann. 1906. Vol. III., Part I. (pp. 901, price M.22 60, or *£1 2s. 9d.*) and Part II. (pp. 1025, price M. 28, or £1 8s.).

THE imposing size of these two volumes, of 901 and 1025 pages respectively, gives the reader some idea of the encyclopædic character of this great work. The first part of the third volume deals with the various obstetric operations. A short historical sketch of their development is followed by a discussion of the indications for their performance and directions as to how they should be carried out, which are given very fully indeed. There is also a very extensive bibliography at the commencement of each section, and how complete these sections are may be gathered from the fact that the list of papers appended to the account of the induction of premature labour occupies some 28 pages and that on the classical Cæsarean section 45 pages. When we realise that the whole of the first part of this volume is given up to a consideration of obstetrical operations we are not surprised to find that practically everything that can be said has been included. The article on the Induction of Premature Labour, written by Dr. O. Sarwey, is a most admirable monograph. In a series of tables he brings forward some instructive statistics as to the results of this procedure. Of 2200 cases recorded during the 15 years 1890 to 1904, 32, or 1·4 per cent., of the mothers died, of whom 13, or 0·59 per cent., died from septic infection. Of 1721 children born alive 1380, or 80·2 per cent., left the hospital alive. Of 500 children born alive in 12 different institutions after the induction of premature labour, 406, or 81·2 per cent., were still living at the end of their first year of life. A third table brings out the interesting fact that with respect to 938 women with contracted pelves of 1700 deliveries at full term only 587, or 34·5 per cent., of the children were born alive, while of 1078 premature deliveries in the same mothers 775, or 71·9 per cent., of the children were born alive—a very striking difference in favour of the induction of premature labour in such cases. In the section on the various methods of dilating the cervical canal a full description is given of the different means which can be employed, including an account of Bossi's dilator. We notice, however, that the instrument figured is not the latest and best model of this dilator. Dr. Wyder, who contributes this article, is by no means impressed with the instrument and for general use prefers one or other form of the hydrostatic bag. The chapter dealing with delivery of the fœtus by the natural passages by the same authority is especially noticeable for the very excellent manner in which the application of the forceps is described, 100 pages being devoted to this important operation, its indications and dangers.

The editor, Professor von Winckel, writes the article on Braxton Hicks's method of performing bipolar podalic version. The results of 708 cases in which this operation was undertaken in the treatment of placenta prævia show a maternal mortality of 35, or 4·9 per cent., and a fœtal mortality of 185, or 60·2 per cent. One of the most important questions which the practitioner has from time to time to answer is the decision as to the performance of perforation of the head on a living child. Cases must occur occasionally in which the perforation of the living child is absolutely necessary if the life of the mother is to be preserved, but how infrequently such an operation is required, at any rate in a lying-in hospital, is shown by the experience of Professor Pinard who has not had occasion to perform this operation once in 1800 deliveries. That this was not due to any infrequency of cases of contracted pelvis is shown by the fact that in these 1800 cases symphysiotomy was performed 13 times. It is surprising to find no mention of a sharp decapitating hook in the description of this operation and that nothing is said of the operation of subcutaneous symphysiotomy, undoubtedly the best method of practising this procedure. The indications for vaginal Cæsarean section are discussed at great length by its originator, Dr. Dührssen. We need not say that the article is one of great excellence and full of detail. The arguments for and against this operation are set out at considerable length. The chapters on Porro's operation and on Cæsarean section are contributed by Dr. Schenk and Dr. Kleinhans. Dr. Strassmann has written the chapter on the treatment of accidental hæmorrhage and the volume concludes with an article on the various methods of producing anæsthesia in obstetric cases by Dr. Wyder.

The second part is taken up almost entirely by the account of puerperal fever but there are a few other contributions. The first chapter, by the editor, consists of a review of the history of midwifery in the nineteenth century. Following this Dr. von Braun-Fernwald discusses wounds and injuries of the genital organs due to childbirth, inversion of the uterus, and post-partum hæmorrhage; and Dr. Döderlein contributes the last chapter on puerperal affections of the bladder. In this part, as in the first, the similar hospitals. Up to the present there have been a few consultant members of professional eminence on the Hampstead staff, but their office has been just as much of a sinecure as that of a consultant member of the staff of any London general hospital. The King Edward's Hospital Fund for London had intimated to the council of the hospital when it attained its present importance that it would be well advised to change the constitution of its staff from local practitioners to "consultants," although it is noteworthy that the Fund has never committed itself to the definition of a consultant. During 1906 the council considered the matter and it was this event that brought about the meeting and resolutions to which we have referred above. The council appointed a special committee to consider the subject, which reported on February last "that this committee is of opinion that it is desirable to appoint a staff of four consultants of high standing (two surgeons and two physicians), but that under the special circumstances of the Hampstead General Hospital it is important to retain the coöperation on the medical staff of medical men residing in the neighbourhood of the hospital." At the end of last year matters were hurried on by a new factor. The North-West London Hospital was in such severe financial difficulties that it was suggested to close it. The King's Fund, however, took the matter in hand and proposed to the Hampstead Hospital that they should amalgamate and carry on their out-patients department at the North-West London Hospital, where there had been an out-patient practice of about 123,000 a year, whilst the Hampstead attendances of out-patients did not much exceed 21,300. The Fund promised the Hampstead Hospital £1500 a year and other benefits resulting from the amalgamation, but the offer was absolutely conditional on the replacement of the staff by the undefined "consultants" and the inclusion of certain members of the North-West London Hospital staff. After much negotiation the Fund agreed to retain the present medical officers for a period of 18 years from the time of their original election, giving them terms of from five to seven years to run, but it would not agree to the subsequent promotion of the assistant medical officers, although one of these gentlemen holds the Fellowship of the Royal College of Surgeons of England. In fact, it laid down the absolute rule that in future the staff must be "consultants" and not local practitioners, however capable these may be. The hospital council, without referring the matter of amalgamation or staff constitution to the general body of governors, has accepted the terms, including the appointment of three members of the North-West London Hospital staff. The condition precluding the present assistant officers from promotion was the last concession made to the King's Fund and was only carried by one vote, and subsequent events have proved that the council was divided on many points. Meanwhile the local profession as represented by the British Medical Association had been active; a conference was held between its 1906 committee and members of the staffs of the two hospitals concerned, where it was agreed that there was no objection to amalgamation under certain very clear conditions regulating the out-patients and insuring a good local professional representation on the staff and the committee. A meeting of the profession was convened on May 24th to consider these recommendations and so far from supporting them unanimously a motion that the amalgamation was undesirable was only lost by the casting vote of the chairman. At this time the staff of the hospital were trying to support their council as far as they reasonably could in a most trying and delicate position and the local profession were handicapped in their endeavours by not having the staff with them. When, however, the council made its final surrender to the King's Fund the staff decided to make common cause with their outside brethren and at a well-attended professional meeting on July 3rd, under the auspices of the local branch of the British Medical Association, Dr. E. Collingwood Andrews on behalf of the staff rehearsed the position and announced that his colleagues and he had decided to support the motion before the meeting:—

> That this meeting considers the Hampstead General Hospital should always have a staff of local practitioners, and in consideration of this opinion calls upon the members of the medical profession to refuse to accept any office on the staff on terms which are not considered satisfactory by the local profession.

He, moreover, announced that a special meeting of governors and subscribers of the hospital had been convened for July 16th who would be asked to rescind the council's decision and to vote for the continuance of an acting staff of local men with an increased consulting staff. Dr. Andrews, it is suggested, minimised the financial support brought by the North-West London Hospital to the amalgamation scheme, but though an important matter it does not affect the position brought about by the proposals. If these are not carried the staff will resign in a body; if they are carried it appears that the amalgamation scheme will fall to the ground, but we understand that the hospital will not thereby lose the support of the King's Fund. The meeting received the attitude of the staff very favourably, although one or two gentlemen tried to confuse the issue with the out-patient controversy. The resolution was carried *nemine contradicente* and there the matter rests until the meeting of hospital governors has been held. We have only had space to indicate the outline of the matter and shall acquaint our readers with the issue in due course. It is impossible to foretell what this may be as the situation is one of extreme difficulty. There is no doubt, however, that the local profession has had its influence greatly strengthened by the support of the hospital staff. We trust that the governors at the approaching meeting will not be swayed by personal considerations but will record their decision in what they conceive to be the true interests of the hospital's welfare.

MEDICINE AND THE LAW.

Attempted Suicide and the Police at Chelmsford.

A CURIOUS and unaccountable attitude appears to have been adopted by the police authorities at Chelmsford, according to the evidence given at an inquest held there recently. The deceased, a carpenter, had become insane and had cut his throat in the street. He was taken by the police while still alive to the Chelmsford Infirmary and was there attended to, but was not allowed to remain as an in-patient because the police authorities at Chelmsford refuse to permit a constable to remain in the infirmary in charge of a person who has attempted suicide and the authorities of the Chelmsford Infirmary naturally and rightly decline to entertain such patients without police assistance. On the occasion in question the deceased, after receiving surgical aid at the infirmary, was taken by the police to the workhouse infirmary, but there he was refused admission, equally rightly, because he was not a proper subject for poor relief. A medical man who appears to have been summoned to attend him at his home found that his condition required that he should be treated in a hospital, and interesting himself vigorously in the matter persuaded the guardians to stretch a point and to allow him to be admitted to the workhouse infirmary. The guardians passed a special resolution that he should be taken in, but an hour after his arrival he died. The jury at the inquest had before them correspondence between the infirmary board and the police which passed in 1904, in which the board intimated that it could not undertake the care of those who had attempted to commit suicide without the assistance of the police, to which the chief constable had replied that he could not instruct the police not to take a patient whose life was in danger to the infirmary if that was the nearest available place, but that it would be detrimental to the public service to allow his men to remain there. They had also evidence to the effect that the institution had no male attendants to take care of such cases as that described and that would-be suicides were admitted to London hospitals only because the police always remained in charge of persons for whose safety they were directly responsible. In reply to this the deputy chief constable is reported to have made the statement that "there is no power to put the police in charge." The jury at the conclusion of the inquest returned a verdict of suicide during temporary insanity, with a rider that the guardians should have been notified of the correspondence between the police and the infirmary, that the guardians were greatly to blame, and that the relieving officer was not to blame as he had only done his duty. Such censure seems to be undeserved and misplaced. The guardians of the union appear to have acted with humanity and to have done their best for the deceased when they were fully informed that his life was in danger, although, strictly speaking, he would not in other circumstances have constituted a case for treatment und-questions considered in the section on Forensic Medicine are: The Bases for Expert Testimony; Insane Heredity and Suicide in Relation to Testamentary Capacity; the Feeble-minded Criminal; the Legal Aspects of Epilepsy; and the Illinois Procedure in Annulment of Marriage for Prior Insanity.

The Seaside and Inland A B C Holiday Guide for the United Kingdom. London: The Wentworth Publishing Company. 1907 Edition. Price 6*d.* net.—This is a useful little book of reference. It contains concise accounts interspersed with photoprints of the chief British holiday resorts, inland and seaside, arranged in alphabetical order. At the end is an index of the golf courses of the United Kingdom and of the angling stations. We note that it is claimed for Hastings that it heads the list for all England as regards its record of sunshine. We may remind our readers of the lists which appeared in THE LANCET on Jan. 26th, 1907 (p. 243), and March 9th, 1907 (p. 676), and we may be excused for doing so as we are sure that many people contemplating their holidays will be glad to study the sunshine records after the gloomy weather which we have experienced lately. It may not be necessary then to take too seriously the announcements of a certain radiant heat and light treatment to which over-frequent attention is called throughout the book.

JOURNALS AND MAGAZINES.

The Asylum News.—The June number of this journal contains a full account of the annual meeting of the Asylum Workers' Association under the presidency of Sir William Collins. In his interesting presidential address he briefly reviewed the ethics of asylum work and the reform which had taken place in the treatment of the insane since the days of Hogarth. Although dealing chiefly with the ethical side of asylum nursing Sir William Collins also gave some sound advice in respect of the intellectual aspect of this special work. The address was excellent both in diction and matter and was in every way eminently suited to the audience. The annual report for 1906 of the Asylum Workers' Association is also published in this number of the *Asylum News* and it shows what active work is being done by this body for the welfare of its members. The Bills before Parliament concerning the registration of nurses have been carefully watched in the interest of asylum nurses, both male and female. During the year 1906 the questions of housing accommodation for married attendants and pensions for asylum workers have been under the consideration of the executive committee and the report indicates that everything is being done to bring these matters to the notice of the Government.

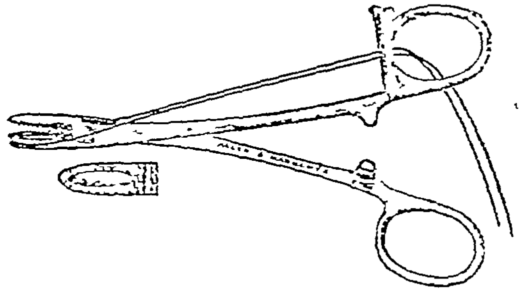
Caledonian Medical Journal.—The first of the original articles in the July number is entitled "The Rôle of the General Practitioner in the Advancement of Medical Science." The author is Dr. James Mackenzie of Burnley who says that there are great questions which are not likely to be solved until the general practitioner takes his share in systematic research. Examples of this kind are to be found in the observation of the progressive development of chronic ailments and in the recognition of that stage of disease when the prospect of successful treatment has passed. Dr. Keith Norman Macdonald relates many reminiscences of the medical curriculum at the University of Edinburgh in the early "fifties." Colonel Kenneth Macleod, I.M.S., contributes a sketch of the Indian medical administration through many stages of development from the year 1600 to the present day. In the editorial paragraphs it is announced that the annual meeting of the Caledonian Medical Society will be held at Bradford on July 25th.

The American Journal of Insanity (April).—Among the several interesting papers in this number of the *American Journal of Insanity*, the following call for special attention. Dr. Solomon C. Fuller's paper on a Study of the Neurofibrils in Dementia Paralytica, Dementia Senilis, Chronic Alcoholism, Cerebral Lues, and Microcephalic Idiocy is an instructive digest on this subject and is accompanied by 13 excellent plates. Dr. O. Lee Carlisle's article on Maniacal Conditions in Young Adults deals with the differential diagnosis between the non-deteriorative and the deteriorative psychoses. He clearly shows the clinical distinctions between the symptom complex known as manic-depressive insanity and the katatonic excitement in dementia præcox. Dr. William Macdonald contributes a paper entitled, "General Paresis or Cerebral Syphilis?" It is written to warn the student not to accept too readily the statement commonly found in text-books that "cerebral syphilis and paretic dementia are diseases which can be readily differentiated from each other." Dr. G. A. Smith supplies an excellent paper on the Application of the Cottage System to the New Hospital. Dr. Smith states that he has had 20 years' experience of the colony system as applied to the care of the insane, and he evidently strongly commends it as giving the most satisfactory results alike with regard to treatment, occupation, and proper classification of the patients. The journal also contains a most interesting letter from a French correspondent on medico-legal expert testimony. He writes that in France experts in criminal matters are named according to the following rules: At the beginning of each judicial year the Courts of Appeal name from the lists proposed by the tribunes of first instance within their jurisdiction doctors of medicine on whom they confer the title of "court experts." In order to be named a candidate must have practised medicine at least five years or hold a diploma for medico-legal studies. Expert physicians named on these conditions by the courts are, in principle, the only ones to whom an expert report can be intrusted. The expert is not allowed to receive any fee for his services if he appears in court as a witness. He is paid from the public Treasury and the payments are according to a scale which is by no means a liberal one. The French expert is never invited to take the part of either the prosecution or the defence, as his fundamental quality is to be impartial. It is evidently recognised in France that the occupation of expert is an important and difficult one and recently the Universities of Paris and Lyons have taken up the special instruction of the medico-legal physician.

New Inventions.

ARTERY FORCEPS AND LIGATURE COMBINED.

THIS forceps, suggested by Dr. Schoemaker of the Hague Hospital, has for its principal feature an ingenious device by which the application of a ligature to a severed artery is greatly facilitated. As shown in the accompanying illustration, the middle of the ligature, which must be more than twice as long as the forceps, rests in a notch at the extremity of one of the blades, whilst the free ends after being tied loosely into the first half of an ordinary



Leith. The six fatal cases of diphtheria showed an excess of three over the number in the previous week, and included four in Glasgow, where the five deaths from measles also were recorded. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had declined from 106 to 72 in the four preceding weeks, rose again last week to 80, and exceeded by 28 the number in the corresponding period of last year. The causes of 24, or 4·8 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 24·3, 20·8, and 19·5 per 1000 in the three preceding weeks, further declined to 18·3 per 1000 in the week ending July 6th. During the 13 weeks ending June 29th the death-rate averaged 25·4 per 1000, the rates during the same period being 14·6 in London and 17·1 in Edinburgh. The 137 deaths of Dublin residents registered during the week showed a decline of nine from the number in the previous week, and included 19 which were referred to the principal epidemic diseases, against 19 and 11 in the two preceding weeks; of these, nine resulted from whooping-cough, six from measles, two from scarlet fever, one from diphtheria, and one from "fever," but not any from small-pox or from diarrhœa. These 19 deaths were equal to an annual rate of 2·5 per 1000, the death-rate last week from the principal epidemic diseases being 1·1 in London and 0·5 in Edinburgh. The deaths from whooping-cough, which had been five and eight in the two preceding weeks, further rose last week to nine; while the deaths from measles numbered six, against three, nine, and one in the three previous weeks. The 137 deaths from all causes in Dublin last week included 24 of children under one year of age and 32 of persons aged upwards of 60 years; the deaths of infants were equal to the number in the preceding week, while those of elderly persons were slightly in excess. Four inquest cases and four deaths from violence were registered; and 59, or 43 per cent., of the deaths occurred in public institutions. The cause of one death in Dublin last week was not certified; in London also only one death was uncertified; while in Edinburgh the proportion was 5·5 per cent. of the total deaths. The 144 deaths in Belfast last week included five which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon: C. M. Beadnell to the *President*, additional, for three months' course at West London Hospital. Surgeon: M. J. Laffan to the *Speedwell*, lent, temporary.

ROYAL ARMY MEDICAL CORPS.

The notification regarding the retirement on retired pay of Lieutenant-Colonel John L. Hall, which appeared in the *Gazette* of June 7th, 1907, is cancelled.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Thomas Price Thomas to be Lieutenant (dated June 18th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Durham (Seaham): Surgeon-Major David Todd, from the 1st Durham Royal Garrison Artillery (Volunteers), to be Surgeon-Major (dated May 29th, 1907).

Rifle: 3rd Volunteer Battalion, The Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant P. G. McReddie resigns his commission (dated June 4th, 1907). 2nd (Angus) Volunteer Battalion, The Black Watch (Royal Highlanders): Supernumerary Surgeon-Lieutenant-Colonel J. K. Anderson (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Black Watch Volunteer Infantry Brigade), is granted the honorary rank of Surgeon-Colonel (dated June 6th, 1907).

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on July 9th, Sir Inigo Thomas in the chair, the sum of £60 was distributed among the several applicants.

EXAMINATION OF MAJORS OF THE ROYAL ARMY MEDICAL CORPS FOR PROMOTION.

The subjects selected for the year 1908 for the examination of Majors, R.A.M.C., for promotion to the rank of Lieutenant-Colonel are as follows: Subject 3 (*a*): The medical history of the more important campaigns and the lessons to be learnt therefrom; the medical history of the Afghan Campaign, with especial reference to the march from Cabul to Candahar; and the medical history of the advance of Lord Roberts to Bloemfontein. Books recommended: "Diary (Medical) of the March of the Field Force of Lieutenant-General Sir Frederick Roberts, V.C., G.C.B., from Cabul to Candahar" (Army Medical Department Report for 1879); "Special Report on the Hospital Organisation, Sanitation, and Medical History of the Wars in Afghanistan, 1878–79–80" (Army Medical Department Report for 1880); "Forty-one Years in India," by Lord Roberts, V.C., chapters 59–62 (thirty-fifth edition, 1902, Vol. II.); "Report on the Medical Arrangements in the South African War," by Surgeon-General Sir William D. Wilson, K.C.M.G., first 44 pages; "The *Times* History of the War in South Africa, 1899–1900," Vol. III., chapters 12 to 15 and chapter 17. *Subject 3 (b)—A knowledge of the Army Medical Services* of the more important Powers: The medical organisation of the French and Italian Armies, as described in the "Handbook of the Medical Organisations of Foreign Armies, 1902."

ROYAL ARMY MEDICAL CORPS IN INDIA.

Under the Indian commands reorganisation scheme it is ordered that: (*a*) The appointments of principal medical officer, personal assistant to the principal medical officer, sanitary officer, and staff officer, Army Bearer Corps, in each command, and of sanitary officer and staff officer, Army Bearer Corps, in the Secunderabad Division and Burma will be abolished. (*b*) The principal medical officers of the three divisions will be surgeon-generals, their pay being fixed at 2200 rupees per mensem, consolidated. (*c*) Two temporary administrative posts will be created, each to be held by a colonel—viz.: one for the Allahabad and the second for the Secunderabad brigades, infantry and cavalry. (*d*) A colonel will be appointed deputy to the principal medical officer of His Majesty's forces in India, his pay being fixed at 1800 rupees a month, consolidated. (*e*) A sanitary officer will be appointed in each office of the nine divisions and in Burma, the staff pay being fixed at 300 rupees per mensem. (*f*) A staff officer for medical mobilisation stores will be appointed in each of the nine divisions (excluding Burma), the staff pay being fixed at 300 rupees per mensen. (*g*) Owing to the above changes the establishments of medical services in India will be reduced by a number of officers corresponding to the number of cadre appointments abolished. (*h*) Existing lady superintendents will, under the orders of the principal medical officer of His Majesty's forces in India, be distributed to the charge of four circles, as follows: First Circle, comprising Peshawur, Rawul Pindi, and Lahore Divisions; Second Circle, comprising Meerut and Lucknow Divisions; Third Circle, comprising Quetta, Mhow, and Poona Divisions; Fourth Circle, comprising Secunderabad Division and Burma. (*i*) Orders regarding the disposal of clerks and establishments of the medical division officers at command headquarters will be issued by the principal medical officer, His Majesty's forces in India.

WEST AFRICAN MEDICAL STAFF.—The first dinner of the West African Medical Staff took place on July 3rd at the Trocadéro Restaurant. There was a large attendance of medical officers, including Dr. W. T. Prout, C.M.G., late principal medical officer of Sierra Leone, who presided; Mr. W. H. Langley, C.M.G., principal medical officer of the Gold Coast; Mr. R. M. Forde, principal medical officer of Sierra Leone; Dr. Hood, principal medical officer of Gambia; Mr. E. Langley Hunt, C.M.G., and others. After the toast of "His Majesty the King" had been honoured, Dr. Prout proposed, "Success to the West African Medical Staff dinner and prosperity to the Staff," and briefly pointed out the advantages of such social gatherings in promoting a feeling of union and cohesion among the members of the staff. It was decided that a dinner should be held twice a year, the next one to take place on the last Wednesday of January, 1908.

THE LANCET.

LONDON: SATURDAY, JULY 13, 1907.

Compulsory Notification of Cerebro-spinal Fever in London.

THE London County Council received on June 18th an important report from its public health committee on the notification of cerebro-spinal fever or epidemic cerebro-spinal meningitis. At the Council's initiative notification of this disease has already been made obligatory in London for a period of six months which began on March 12th last. Cerebro-spinal fever, so far as it is related to season, shows a greater prevalence in the early months of the year, and it is now proposed to extend the period of compulsory notification for two additional years in such a way as to cover two possible epidemic periods. This proposal has much to commend it. The experience of recent years shows that in the United Kingdom cerebro-spinal meningitis is not at present to be regarded as a disease which becomes frequently or readily diffused. Here and there in particular localities or households the disease has spread with great rapidity and intensity, in circumstances apparently not unlike those in which typhus fever sometimes shows marked infective ability. Infection from person to person by the meningococcus of Weichselbaum is usually, and probably rightly, suspected to occur in these cases, but we are not yet able to assert that such infection constitutes the principal agency responsible for these specially infective outbreaks. In sporadic cases direct association with previous cases of meningitis has seldom been traced. The part played by intermediate "carrier" cases in the spread of meningitis, like the question of the dependence of the disease on mixed infection, is as yet hardly beyond the stage of speculation. In these circumstances the fact that compulsory notification affords a means of securing the isolation of the patient, the segregation of "contacts," and the disinfection of the dwelling does not constitute the chief reason for this administrative measure. The principal value of notification in London at the present time is that, with coöperation between hospital physicians and medical practitioners on the one hand and medical officers of health and bacteriologists on the other, new facts may be obtained which will throw light on the circumstances in which this highly fatal disease occurs in sporadic form or in which on occasion it becomes intensely infective. This aspect of the question has been realised by the public health committee which recommends that with the continuance of notification in London a small fund should be set aside for investigatory work under the direction of Sir SHIRLEY F. MURPHY and his colleagues in the medical department of the County Council.

Meningitis, both in adults and children, may be connected with a variety of conditions which clinically and etiologically have to be kept apart from "cerebro-spinal fever." The report points out that the term "cerebro-spinal fever" as regards notification to the health authorities is not to be interpreted to include cases of meningitis due to tubercle, syphilis, middle-ear disease, or injury. In regard to so called "simple" meningitis, and particularly posterior basal meningitis (cervical opisthotonos of infants), the case is different. Dr. A. K. CHALMERS has shown that in Glasgow since attention has been prominently directed by notification to "epidemic" cerebro-spinal disease, many deaths which in ordinary years would have been ascribed to "simple" meningitis or posterior basal meningitis have been registered as due to "cerebro-spinal fever." And from the investigations of Dr. G. F. STILL and others it has for some years been known that the meningococcus of Weichselbaum is frequently discoverable in the cerebro-spinal fluid of cases of posterior basal meningitis. In consequence of the need for better understanding on this and other matters bearing on compulsory notification, the London County Council has taken the prudent step of consulting, and inviting the assistance of, the Royal College of Physicians of London, and a committee which the President, Sir R. DOUGLAS POWELL, convened to consider the question has expressed the following opinions:—

> We find clinically that although as regards symptomatology and duration there are some differences which might separate the most marked cases of cerebro spinal fever (epidemic cerebro-spinal meningitis) and posterior basal meningitis from one another, nevertheless intermediate cases occur in which such differentiation is impracticable.
>
> It cannot (at present) be maintained by experts with absolute certainty that there is any demonstrable difference in the bacteriology of the two diseases. The organism which is commonly associated with each disease is microscopically the same (meningococcus, micrococcus intracellularis, diplococcus intracellularis meningitidis), such variations as may be met with being dependent on minor differences in cultural characters.
>
> It is noteworthy that, so far as has been ascertained at present, both diseases tend to occur during the earlier months of the year, and that, although the occurrence of the disease in both instances is epidemic, in neither has it the characteristics of a spreading malady.

In view of these considerations and on the advice of Sir R. DOUGLAS POWELL'S committee the County Council proposes to take steps to inform medical practitioners in the metropolitan area that for notification purposes the disease at present known as posterior basal meningitis should be included under the term "cerebro-spinal fever." Arrangements are to be made for bacteriological examination of notified cases so far as may be desirable, and the services of Mr. W. M. WANKLYN, assistant medical officer of health, will be made available with a view to the investigation of cases in association with medical practitioners in London should they so desire. The action of the Royal College of Physicians of London in the matter has done much to prepare the way for making satisfactory use of the information which compulsory notification can provide. We are sure that Sir SHIRLEY MURPHY'S department will receive the coöperation which is required for its investigations, not only from metropolitan medical officers of health and medical officers of hospitals, but also from medical practitioners in London who have an opportunity of giving assistance.

the current but simply as high-frequency currents, and have shown that the physiological effects may differ with varying conditions of the patient. The question as to the effects of various kinds of current I have referred to as important; but I have not attempted to discuss this point, preferring to leave it for future investigation by others as well as by myself. Dr. Bowie's knowledge of the subject and his obvious interest in it lead me to hope that he may help in this. Criticism of what has already been done is a good beginning. I am, Sirs, yours faithfully,

Glasgow, July 1st, 1907. SAMUEL SLOAN.

THE SURGICAL TREATMENT OF CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. J. Hopkins Walters in THE LANCET of July 6th, p. 48, would deserve a full reply if it were not intended as a defence of an author well able to take care of himself. Mr. Walters will see that if I allow myself to be drawn into a controversy with him, next week some fourth person may come forward, some unsilent worshipper of Mr. Walters, to declare that I have "utterly misconceived or misrepresented" his letter, that I "cannot have read" that letter, that I have placed him "on a pillory to be stared at or stoned," and so on. Then, in spite of the "rectitude" and "angularity" with which Mr. Walters credits me (why not call it "rectangularity"?), I am really a very polite man and might reply to number four, which would call up number five, and so the struggle continue, descending from "great surgeons" to small, then to still smaller, until in ages to come microscopical surgical knights-errant might be bombarding a myth with emanations, infinitesimal but warm, like those of radium.

It is this consideration which prevents me from more than briefly referring to Mr. Walters's own interesting case. I note that in it the obstinate constipation seems to have come on immediately after a "nervous breakdown." I do not suppose, therefore, that Mr. Walters attributes it to any mechanical obstacle presented by the colon. It was with especial reference to excision of the cæcum that I said that "the condition of the appendix vermiformis" should be "always carefully noted." This is made clear by the context, from which Mr. Walters has removed the words, tacking them on to a preceding paragraph, and putting all between one set of inverted commas. This enables him to report with, as it were, a "there now!" that the appendix was found healthy in his case of simple ileo-sigmoidostomy. He has no wish to misrepresent, I am sure, it is merely a specimen of the light and careless touch by which "rectitude" and "angularity" can be avoided.

In reply to his question whether appendicostomy would have produced excellent results in this case I think it would. With regard to my admission that after appendicostomy the opening should be regularly catheterised he should remember that the mere use of the appendicostomy provides this catheterisation automatically. It is no more a serious drawback than the aperients and enemata to which his patient seems to have had to return after ileo sigmoidostomy.

I am, Sirs, yours faithfully,

C. B. KEETLEY.

July 6th, 1907.

GROCCO'S TRIANGLE: PHYSICAL AND ANATOMICAL EXPLANATION.

To the Editors of THE LANCET.

SIRS,—I have read with pleasure Dr. F. W. Forbes-Ross's article on the above subject in THE LANCET of June 29th, p. 1773, and do not think that he need in any way apologise as a surgeon for his possession of a general knowledge of medicine. It is to be hoped that the specialist who prides himself upon his ignorance of matters beyond the sphere of his principal activity will become rare among us—is, I would fain hope, not common now. There are a few points in Dr. Forbes-Ross's paper and Dr. W. Ewart's letter in THE LANCET of July 6th, p. 49, which provoke comment.

In the first place, and with every disposition to do homage to those who add to our knowledge, there is manifestly an inconvenience in the use of a patronymic nomenclature of structure or disease. Surely it would be more informing were a term used which denoted a presumably recurrent condition rather than that such should be only appreciated by reference to a biographical dictionary or by more or less archæological research. "Grocco's triangle" is represented as being an area of communicated percussion dulness beyond or beside a medium of lower vibrational capacity than that through which it is conducted to the surface. I am aware that I am rather at variance with Dr. Forbes-Ross on this question of physics but do not propose discussing this point at present, as it is not material to the remarks I propose making.

"Grocco's triangle," if it be such as it is represented as being, is a *parachumatic* percussion dulness. I hope I may be forgiven for using so uneuphonious, yet, I think, quite correct a term, denoting beside or near (*παρα*) an effusion (*χυμα-ατος*). Parachumatic percussion dulness may be an all-important or an altogether subsidiary sign. In the cases referred to by Dr. Forbes Ross and Dr. Ewart it is, I think it will be admitted, of little importance. The conditions stated to manifest it are abundantly evident from other signs. The cases mentioned by Dr. Ewart in which "amounts of (fluid) too small to be identified by any other means," are only thus discoverable must be of rare occurrence. The diagnosis, again, of enlarged bronchial glands in the posterior mediastinum in "incipient cases of tuberculosis" by a "sudden spread" of Grocco's triangle, as pointed out by Dr. Forbes-Ross, is, I confess, a refinement of diagnosis which extorts my admiration but also one which I should hesitate to accept as correct without more definite and other evidence. The chief circumstances in which parachumatic percussion dulness in the thorax may be of great importance are, in my experience, those attendant upon some cases of *subdiaphragmatic suppuration.* An abscess creeping up behind or above the liver and raising the diaphragm (as in Dr. Ewart's cases of ascites showing symmetrical paravertebral triangles of dulness) may be associated with parachumatic dulness at the right pulmonary base posteriorly and with obscuration of the respiration in the area of such dulness. The discrimination of this state from one of primary pleural or pleuro-pneumonic disease lies chiefly in the fact that the constitutional disturbance is out of all proportion to the local thoracic signs, while hepatic and abdominal evidences of the causal condition may be altogether absent. In these circumstances this parachumatic dulness, whatever its shape, is frequently pathognomonic of the serious subdiaphragmatic condition in question and a reliable guide to the measures indicated for the relief of the patient, which are, of course, surgical. In conclusion, Sirs, I hope these remarks will in no wise be regarded as expressing any want of appreciation on my part of the interest of Dr. Forbes-Ross's communication which has the charm of all anatomical elucidations.

I am, Sirs, yours faithfully,

ALEXANDER MORISON.

Upper Berkeley street, W., July 6th, 1907.

PROPOSED AMALGAMATION OF THE NORTH-WEST LONDON HOSPITAL WITH THE HAMPSTEAD GENERAL HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I venture to ask if you will kindly allow me to correct the statement which Dr. E. Collingwood Andrews is reported to have made in his speech at the meeting of the Hampstead division, Metropolitan Counties Branch, British Medical Association, on July 3rd in reference to the assets which the North-West London Hospital might be expected to bring into the proposed partnership. Dr. Andrews would have his supporters believe that the only financial help to be given by the North-West London Hospital would be "to the extent of about £200 a year by subscribers." In this Dr. Andrews is very wide of the mark, and it is to be regretted that apparently there was no one at the meeting sufficiently well informed to correct this mis-statement.

As a matter of fact, my committee is prepared at this moment to hand over investments and cash balance at the bank to the amount of over £5500, with "stock in trade," which includes surgical instruments valued at £400. Last year (an average year) our annual subscriptions were £754, donations (apart from the King's Fund, the Hospital Sunday and Saturday Funds) £1128. Many of these donations may be regarded as regular income, although they do not appear under the heading of annual subscriptions. The average annual income for the past few years has been nearly £5000.

their illness was concealed from them under a mist of minimising words? How many diabetics would restrain their appetites, how many of the subjects of syphilis would abstain from marriage and would submit to a mercurial course of the necessary character and duration unless the urgency of the several cases were driven home by clear statements of the facts? Every practitioner will meet with times in which to keep silence; but he will also, and far more frequently, meet with times in which to speak. The increasingly scientific character of medicine is imparting, year by year, a greater amount of certainty to its predictions; and just in proportion as such certainty is attainable will be the urgency of the duty of not concealing from the patient any facts about his condition a knowledge of which may be essential for his guidance. There will always be abundant room for the exercise of discretion; and prudence may often require disclosures to be gradual and manifestly the results of continued study of the evidence. But the fact that some few individuals may seek refuge in death from the irksomeness and the anxiety of a struggle with disease is one that has no real bearing upon the question at issue. The ordinary patient must be brought into a sort of intellectual partnership with the practitioner before he can derive full advantage from the knowledge that is being exerted for the purpose of accomplishing his cure.

◆

The Imaginative Temper in Science.

A DISTINGUISHED Churchman and biologist has given to an exceptionally able work the suggestive title of "The Scientific Temper in Religion," and this idea so exactly embodies another relationship to which we have occasion to call attention that we make bold to annex and adapt his phrase. The occasion to which we allude is afforded by reading some words that fell from Mr. RIDER HAGGARD when recently distributing the prizes to the students of St. Thomas's Hospital Medical School. Mr. HAGGARD exhorted his hearers to fit themselves for their responsibility as scientific practitioners by cultivating, amongst other qualities, their imagination. We consider that Mr. HAGGARD was giving a remarkably good piece of advice, provided always that those who follow it allow their pursuit of science to be not dominated by imagination but tempered with it. The importance of this faculty in relation to science may not be clear to all. Some certainly will tell us that imagination is for the poet—that it is such a spirit as, at the call of the nightingale, transported our famous singer from his Hampstead garden to the forest of Faery "when June was June" a century ago. That spirit was not imagination but fancy. Imagination has more affinity to science, to true constructive science, which transcends the bare collection of facts. Indeed, it may almost be said of the great masters of science who revolutionised their own domains that they were endowed with an imaginative grasp of their subject that gave them a well nigh prophetic insight to its deepest mysteries; and this insight has served them for an ever- h that the minute researches to which they have devoted their lives would one day result in the introduction to the world of thought of a grand and glowing truth the faint image of which had been revealed to them, though darkly, in the glass of their imagination many years before. But herein they showed themselves to be men of science and not dreamers, that before they presented their great gifts to the world they had searchingly and patiently applied to them the touchstone of experiment and ofttimes modified them again and again from their original crude forms; in a word, their imagination was their servant and not their master. For illustration many great names occur. Even though the story of NEWTON'S apple be apocryphal, yet it serves to remind us that he was endowed with an imagination which could conceive of a law of cosmic unity of stupendous import and which had power to urge him to direct the light of his vast intellect upon its elucidation. Will any deny imagination to the scientific faith that in later years confidently announced the existence of an unknown planet with an importunity that met with a triumphant justification? Or if we turn to the sphere of biology, the temper of imagination enters so prominently into the life work of DARWIN and PASTEUR that we are almost tempted to believe that it was this one faculty which lifted them so high above the many great investigators of their century. In the case of the father of bacteriology the insight which led him on from the study of the crystallography of tartaric acid to that of fermentation in plants and thence to the bacterial conception of disease is a pure example of what we mean by the imaginative temper in science.

Many more names might be cited in illustration of this subtle influence in the history of scientific progress but we are constrained to pass to the consideration of the other and dark side of the picture. We are told that "The heathen have imagined a vain thing," and unfortunately that saying is true of the workings of many modern imaginations; indeed, there are far more instances of the unscientific temper in imagination than of the opposite quality of which we have attempted to show the value. The reason why people do harm by imagining vain things is that they will not take the trouble to control their imaginations by the one safe method of laborious and impartial experiment. Let us consider one outstanding example. It was found that certain drugs when administered in minute doses had a controlling action over certain symptoms of disease resembling in each case those produced by the action of the drug on the healthy body. By the exercise of an imagination which was certainly legitimate the founder of homœopathy conceived that all drugs might have this action; if he had only tried them, he would have found that they had not, but instead of doing so he let his imagination get the upper hand and enunciated a general principle which had the unfortunate effect of burdening medicine with a new sect and of producing a considerable amount of professional bitterness. We have amongst us at the present day many beliefs which depend on a distorted imagination, as Mr. HAGGARD reminded his audience at St. Thomas's Hospital, such as that modern distortion of Christianity which goes by the name of "Christian Science," and the effects of those imaginings have been more than once exposed in our law courts, but perhaps it would be fairer to the noble faculty of imagination to class such to obtaining this new diploma from the society the qualification can be entered upon the Medical Register. The form of the new diploma and other matters connected therewith are at the present time under the consideration of the Court of Assistants of the Society, and I hope to be in a position to make a definite statement as to the Society's requirements in the course of next month.

I am, Sirs, yours faithfully,
A. MOWBRAY UPTON,
Clerk to the Society.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.

(*With Reproductions of Photographs taken by the Author.*)

X.[1]

THE ABU-SAAD LAZARET.

Position and Object of the Lazaret.—Question of its Transfer Elsewhere.—Proposed Annexe on the Mainland.—Statistics of Pilgrims Quarantined there.—Means of Landing; Sambouks and Tug; Landing Piers.—Disinfecting Pavilion.—Need of Wire Fencing Round the Different Cordons.—Stone Houses for Pilgrims.—Total Capacity of Lazaret.—The Drinking-water Supply; New Distilling Apparatus; Mode of Distribution.—Sea-water Supply.—Latrine Jetties, Old and New.—Absence of Hospitals; New Hospital for Ordinary Diseases to be Built on Abu-Saad; Space for a Second One left on Wasta; Infectious Diseases Hospital on Abu-Ali.—Staff of the Lazaret and Mode of Lodging them.—Other Buildings.—Estimated Cost of New Works.—Return of the Pilgrims from Mecca to Jeddah and their Departure for Yanbo or for their Own Countries.

THE lazaret of the port of Jeddah is commonly known as the Abu-Saad lazaret, that being the name of the principal of the three islands upon which it is built. The others are named Wasta and Abu-Ali. The so-called "port" of Jeddah is merely an anchorage, or rather two anchorages, an "inner" and an "outer port," among the shoals and coral reefs which characterise the whole of this coast. These reefs are very irregular but their long axes run more or less parallel with the coast. The "outer port" is about two and a quarter sea-miles from the shore and the "inner port" about one and a quarter miles in a straight line, but no boat, however shallow its draught, could reach the shore by following a straight line, and the only available channel takes an extremely zigzag course among the reefs. From the inner port to the island of Abu-Saad the distance is three and three-quarters sea-miles, from Abu-Saad to Wasta it is one and three-quarters miles, and from Wasta to Abu-Ali one and a quarter miles. The three islands lie to the south of the town and are roughly about two miles from the mainland. Ships in quarantine remain in one or other of the anchorages at Jeddah and their pilgrims are transferred to the lazaret in sambouks.

The Abu-Saad lazaret was brought into existence in 1882 as a "succursale" of the much larger institution at Camaran. It is intended for the use of ships carrying not more than 5 per cent. of their net tonnage coming either from the north or from the south. Ships with a larger number of pilgrims are liable to be sent to Camaran, but this usually happens only in the case of ships from the south. The latter are always subject to from five to ten days' quarantine, and they have in any case to pass close to Camaran on their voyage to the Hedjaz. But ships from the north are only liable to quarantine when Egypt or some of the countries on the Mediterranean are infected with plague or cholera. This happened in 1902–03, in 1905, and again in 1906–07 (the Haj just completed). On the two earlier of these three occasions the Egyptian lazaret of El Tor was used for pilgrims going to the Hedjaz from the north by agreement with the Alexandria Quarantine Board. In the present Haj, however, the pilgrims have been sent to the Abu-Saad lazaret. The Commission of Inspection has gone very carefully and fully into the figures, and these show that when there is not more than two days' quarantine in force against Egypt or other "northern" country the Abu-Saad lazaret is capable of providing sufficient accommodation, but when the quarantine extends to five days then the accumulation of pilgrims is likely to be such that the Abu-Saad institution is quite inadequate to hold them.

It has more than once been proposed to transfer this lazaret to a spot where more ample accommodation could be provided than is possible on the three small islands named above. Unfortunately, no other suitable spot has yet been found; to this point I shall have occasion to refer again in the article dealing with El Wej. For many reasons the entire transfer of the lazaret is undesirable and as there are equally cogent reasons against the use of Tor (for pilgrims going *to* the Hedjaz) and against the repulsion of ships from the north to Camaran the Commission proposes to meet the difficulty by providing an annexe on the mainland to the lazaret on the three islands near Jeddah. Such annexe would only be required on the occasions when there was a quarantine of more than two days against Egypt, and then only for the two or three weeks immediately preceding the fêtes at Mecca, in which the Haj culminates. At other times the three islands should suffice.

The lazaret of Abu Saad differs from that of Camaran, firstly, in being open all the year round, and secondly, in the very wide fluctuations in the number of pilgrims it may be called on to receive in the year (depending mainly upon the presence or absence of quarantine against Egypt or other "northern" country). These fluctuations are shown in the following table:—

Table giving the Annual Totals of Pilgrims Interned in the Abu Saad Lazaret.

Year.		Pilgrims.	Year.		Pilgrims.
Of the Hegira.	A.D.		Of the Hegira.	A.D.	
1299	1882	5,435	1312	1895	9,437
1300	1883	4,894	1313	1895–1896	23,304
1301	1884	3,988	1314	1896–1897	13,076
1302	1885	3,286	1315	1897–1898	1,766
1303	1886	2,181	1316	1898–1899	1,852
1304	1887	3,519	1317	1899–1900	3,726
1305	1888	2 578	1318	1900–1901	1,103
1306	1889	4,021	1319	1901–1902	21,625
1307	1890	12,862	1320	1902–1903	3,662
1308	1891	4,602	1321	1903–1904	2,733
1309	1892	4,674	1322	1904–1905	10,209
1310	1893	6,525	1323	1905–1906	2,624
1311	1894	5,567	—	—	—

The three islands on which (or, to speak more accurately, on two of which) the lazaret is at present built are typical small coral islands. Abu-Ali is smaller than Wasta but larger than Abu-Saad. The disadvantages arising not only from the smallness of the islands, but also from the fact that the lazaret is thus split up into sections, separated by wide stretches of water, are too obvious to need dwelling on. For the purposes of communication between the lazaret and the town and between the different portions of the lazaret the sanitary authorities possess a steam-tug, the *Zulal*, a small steam launch, and a four-oared sailing boat. The steam launch, however, can never with safety leave the "port" of Jeddah, and it and the sailing boat are practically limited to carrying out the requirements of the service in the port. The *Zulal* is a small but powerful steam-tug; it is used for towing the sambouks in which, as already stated, the pilgrims are carried to the lazaret from their steamers. The Commission finds that there is need for additional means of establishing communication between the different parts of the lazaret and its recommendation for the purchase of another large four-oared boat has been already carried out.

There is a stone landing-stage at Abu-Saad and another at Wasta, but none at Abu-Ali. Both the existing stages were found in a bad state of repair and to need lengthening; the necessary works were put in hand during the past summer and both have now been thoroughly repaired and prolonged the part of a large number of persons in the adequate management of the hospitals—has been largely attained. Grants have been made to several hospitals situated within the home counties, but outside the area of distribution of the King's Fund. In 1906 these amounted to about £500 and were paid direct to the hospitals after inspection and report. It is contemplated that a larger sum shall be so awarded during the current year." The work of the league is carried on by a network of some 106 "districts" spread over London and the home counties. Nearly every Parliamentary division within this area has its branch of the league, but even yet the organisation of its machinery is not fully completed. There are, however, 182 presidents and lady presidents working under T.R.H. the Prince and Princess of Wales as Grand President and Lady Grand President. Under these, and in coöperation with them, are some 1200 ladies and gentlemen acting as vice-presidents and lady vice-presidents and directing the work of some 20,000 members of the league who in their turn have enrolled as associates—that is to say, subscribers of from 1*s.* a year and upwards—more than 200,000 men, women, and children. Every shilling so subscribed goes directly to the hospitals without any deduction.

GIUSEPPE GARIBALDI.

JUST 25 years ago[1] we commented on the life and work of the Italian hero then lost to his country and compatriots; and now, when the Italian world, and much that is outside it, has been celebrating the first centenary of his birth we return to the theme. That interval of a quarter of a century has in no wise modified our estimate of the man, nay, as in the case of the mighty statesman Cavour and the soldier king Victor Emanuel, whose policy he helped to carry out, his figure stands forth larger and nobler from the background of years. Intellectually there have been popular leaders far superior to Garibaldi; morally, in heart and soul, few have been so richly endowed. His judgment was frequently at fault; so much so that when his impulse got the better of his prudence Cavour's successor, Massimo d'Azeglio, could say of him: "Garibaldi has the heart of an angel and the head of a buffalo." When he took the field on his own account he almost uniformly failed; when he was following out, consciously or unconsciously, the policy of Cavour he brilliantly succeeded. Not that his failures were without wholesome fruit. Generous initiative is never thrown away, and even his abortive raids on the Temporal Power in 1862 and 1867, as Gregorovius, Rome's great historian, has proved, gave a turn to events which not long after issued in the triumph of the cause which he had at heart. That cause consummated, he, like Cavour before him, sought to educe from it the development of the country's resources, above all, the resuscitation, the ennobling of the nation's character. "We have made Italy," said d'Azeglio, "we have now to make Italians," and in that spirit he set to work. In the January of 1875 he left his island rock for Rome, took his seat in Parliament after taking the oath of fealty to the King, and lost no time in impressing on his compatriots their need for moral, material, ay, even physical rehabilitation. To a dense audience of Romans assembled in the mausoleum of Augustus he conveyed many home-truths—among others this: "What you want is the English steadiness," a lesson which, in the opinion of many Italians, they have yet to learn; and to accelerate that consummation he "began at the beginning," urging the erection of schools, and showing the example of starting them with the aid of English subscribers in the neighbourhood of his island rock. As to his schemes for reclaiming the Campagna—deflecting the Tiber into the Anio and carrying their united waters round the city into the sea—they never survived the criticism of the great engineer Brioschi, but, all the same, they brought to the front the crying need for the agricultural restoration of the Agro Romano to the productiveness and the salubrity which it enjoyed under the Antonines when the "vegetative energy" of the soil was duly absorbed by cultivation and no "intoxication tellurique" found (or created) a congenial "carrier" in the mosquito. In the same spirit he sought to improve the national physique by a wise and systematic athleticism, and here again his initiative has borne fruit till we see football clubs and outdoor "palaestrae" beginning in Piedmont and gradually penetrating to other provinces and the movement for physical regeneration acquiring such proportions that Rome is to be the seat, next October, of a great congress of "Terapia Fisica," at which every nationality that can assist its object will be represented. The "Good Genius" of that assembly will, indeed, be Giuseppe Garibaldi, who, knight errant as he was, saw other fields for "prowess" than those of war; who, responsive to the delight of battle as the *Re Galantuomo* whom he served, could justify it only as a painful pre-requisite for attaining those conditions under which humanity develops freely and normally and who, in death as in life, is yet a spell potent for the philanthropic ideal:—

> ". . . . . when all men's good
> Is each man's rule, and universal Peace
> Lies like a shaft of light across the land,
> And like a lane of beams athwart the sea,
> Thro' all the circle of the Golden Year."

LATENT MALARIA.

THE *Yale Medical Journal* for June contains an important paper by Dr. C. F. Craig on Latent Malaria—a subject that has not received sufficient attention. By latent malaria is meant infection with the plasmodium malariæ without the production of symptoms of sufficient intensity to attract attention. Dr. Craig's paper is based upon 1653 cases of malaria, of which 1267 were observed in the United States Army Hospital in San Francisco in American soldiers who had returned from the Philippines, and 386 cases observed in the Island of Luzon. Of the latter, 138 cases occurred in natives. Of the 1653 cases 424, or a little over 25 per cent., were latent. The latent infections included all forms of malaria—tertian (110 cases), quartan (8), æstivo-autumnal (297, of which 272 were tertian and 25 quotidian), combined tertian and tertian æstivo-autumnal (7), and combined tertian and quotidian æstivo-autumnal (2). In Americans there were 307 cases (24 per cent.) of latent malaria, of which 220 were due to the tertian or quotidian æstivo-autumnal parasite. The preponderance of this organism is due to the fact that it is more resistant to quinine than the others. From an epidemiological point of view, the importance of recognising latent cases of malaria is great, because a person with latent malaria may be a source of infection to the community in which he lives. Hence the blood of persons returning from a malarious district ought to be examined. The extent to which latent infection may prevail is shown by the following facts. A company of 60 infantry returned to San Francisco after duty in a notoriously malarial region in the Philippines. 14 were in hospital for malaria, and examination of the blood of the remainder who were doing duty showed malarial infection in 27. Of these 25 were infected with æstivo-autumnal plasmodia—13 showing crescents of the tertian type; two showing crescents and ring forms of the quotidian type; and 10 showing crescents and ring forms of the tertian type. These figures are important because they show that the type of plasmodium is the most dangerous one, and that it is usually present in the crescent form, which is intended to

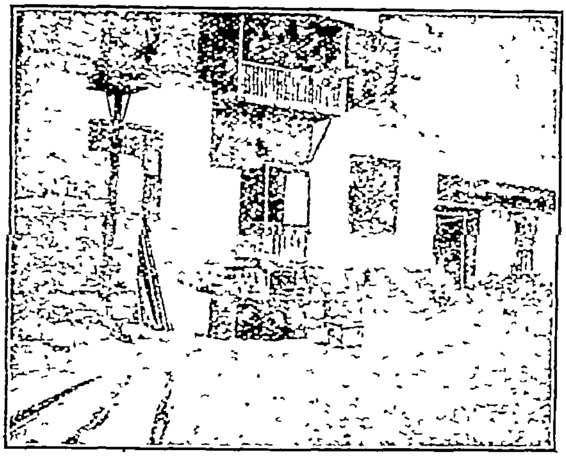
By latent malaria is meant infection with the plasmodium malariæ without the production of symptoms of sufficient intensity to attract attention. Dr. Craig's paper is based upon 1653 cases of malaria, of which 1267 were observed in the United States Army Hospital in San Francisco in American soldiers who had returned from the Philippines, and 386 cases observed in the Island of Luzon. Of the latter, 138 cases occurred in natives. Of the 1653 cases 424, or a little over 25 per cent., were latent. The latent infections included all forms of malaria—tertian (110 cases), quartan (8), æstivo-autumnal (297, of which 272 were tertian and 25 quotidian), combined tertian and tertian æstivo-autumnal (7), and combined tertian and quotidian æstivo-autumnal (2). In Americans there were 307 cases (24 per cent.) of latent malaria, of which 220 were due to the tertian or quotidian æstivo-autumnal parasite. The preponderance of this organism is due to the fact that it is more resistant to quinine than the others. From an epidemiological point of view, the importance of recognising latent cases of malaria is great, because a person with latent malaria may be a source of infection to the community in which he lives. Hence the blood of persons returning from a malarious district ought to be examined. The extent to which latent infection may prevail is shown by the following facts. A company of 60 infantry returned to San Francisco after duty in a notoriously malarial region in the Philippines. 14 were in hospital for malaria, and examination of the blood of the remainder who were doing duty showed malarial infection in 27. Of these 25 were infected with æstivo-autumnal plasmodia—13 showing crescents of the tertian type; two showing crescents and ring forms of the quotidian type; and 10 showing crescents and ring forms of the tertian type. These figures are important because they show that the type of plasmodium is the most dangerous one, and that it is usually present in the crescent form, which is intended to a similar building but in a better state of repair. It has been decided to restore thoroughly this building and to add two new rooms at each end of it; there will thus be four rooms on the ground floor and four on the upper floor, or eight in all. With these additions and the new house at Wasta there will be a sufficient accommodation for the existing staff. The crew of the tug sleep on board, where there are bunks for ten persons.

---

[1] THE LANCET, June 10th, 1882, p. 956.

There remain to be mentioned a few other buildings that form part of this lazaret. On Abu-Saad, close to the landing jetty, is a masonry structure with galvanised iron roof, about 32 feet long by 20 feet wide, which constitutes the only depôt or storeroom that the lazaret possesses. It is rather small for the purpose, but it is difficult to find room for another on any of the islands. It is therefore proposed to build one in Jeddah itself adjoining the sanitary office there, and it will thus serve for the purposes of the office and the lazaret combined. Annexed to the store is a small room in which are a forge, a lathe, and some other machines. On Abu-Saad a stone house to lodge the military guard has recently been built and a second one is provided for in the plan of Wasta.

FIG. 37.



House for staff, Abu-Saad.

Both at Abu-Saad and at Wasta there are small wooden houses occupied by the provision dealer from whom the pilgrims buy their food and various other articles at a fixed tariff. The same dealer, an Arab, has provided the lazaret for the last 18 years. He or his employees remain interned in the lazaret so long as there are any pilgrims quarantined there. The house he occupies on Abu-Saad is in fair repair but that on Wasta is a mere skeleton of wood, and is to be rebuilt on another site, as shown in the sketch map of that island.

There is no railway in this lazaret, as at Camaran, nor is there any need of one, the islands being so small. At present also there is no telephone, and this is a serious disadvantage, in view of the distance of the lazaret from the town and of the individual islands from each other. It has been decided, therefore, to establish telephonic communication both between Jeddah and Abu-Saad and between the different islands.

The total cost of the new works proposed by the Commission for the completion of this lazaret is estimated at about 13,000 Turkish liras (say, £12,000). The more urgently needed works require an expenditure of about 5000 liras, and of these about one-third have already been put in hand since the return of the Commission to Constantinople; the others must of necessity wait until fresh credits can be voted by the proper authority. The works just mentioned as being already put in hand are the following: the construction of a landing-stage at Abu-Ali, the building of one of the hospitals, the putting up of wire fencing on all the islands, so as to establish definitely the plan of the lazaret and the shape and size of the cordons, the carrying out of certain modifications in the disinfecting pavilion, and the introduction of pipes to distribute the fresh water throughout the islands of Abu-Saad and Wasta.

I have now completed the description of the lazarets of Camarán and of Jeddah. These both serve for the quarantining of pilgrims on their way to the Hedjaz. Before passing on to consider some subsidiary ports of pilgrimage in the Red Sea and some quarantine institutions connected with the return of the pilgrims from the Hedjaz a word or two may be said as to the movements of the pilgrims themselves between their arrival in, and departure from, that province. I have already described the nature of the fêtes at Arafat and Mina in which the Haj or pilgrimage culminates[3] and the sanitary measures taken in connexion with those fêtes. As soon as they are completed the pilgrims begin to leave Mecca as rapidly as the authorities and the supply of camels permit them to do so. As a matter of fact, a few days generally elapse between their return from Mina to Mecca and the departure of the first caravan from the latter town, either for Jeddah or Medina. Sooner or later two streams of caravans form, the one flowing westwards to Jeddah, only 45 miles distant, the other northwards to Medina, at a distance of 12 days' journey in the desert. The delay in starting either of these streams is connected with the chaffering and bargaining inseparable from the hiring of camels for two such journeys.

On returning to Jeddah the pilgrims again split up into numerous groups, but these may be roughly divided into two—those going to Yanbo in order to continue their pilgrimage to Medina and those returning to their homes. The latter comprise, of course, a vast variety of pilgrims, and they leave Jeddah to disperse to all parts of the Moslem world as rapidly as steamers can be provided for them. The former also constitute a very varied and numerous group, their total frequently running up to five figures. At this period the town of Jeddah is in the intensely overcrowded condition described in an earlier article. A delay of some days generally occurs between the arrival of the first caravan from Mecca and the departure of the first steamer. During this interval there is for a day or two much uncertainty as to the price the pilgrims will be charged for their return journey. Several large shipping companies are concerned in the pilgrim traffic, and in some years open competition prevails between them, while in other years a pool or syndicate is formed by mutual arrangement between the companies who then agree to charge the pilgrims the same price all round. When open competition prevails the prices are lower and the conditions more favourable for the pilgrims. A certain number of pilgrims—notably those from the Dutch East Indies—have return tickets and can regard with indifference the question whether competition or the pool is to carry the day. But these are the exception.

Among the pilgrims accumulated at this period in Jeddah there are always many in an almost or quite penniless condition. Some are more or less in that condition from the time they set out on the Haj; others have spent all they had during their stay in the Hedjaz. There is always a difficulty in getting these indigent pilgrims back to their own countries. Generally—and more particularly when the "pool" system prevails—the shipping companies consent to carry on their ships a certain percentage of such pilgrims gratuitously. Others are paid for by their respective Governments or out of charitable funds. And so, little by little, the port of Jeddah empties itself of ships and of pilgrims, and enjoys a few months of repose before the first arrivals of the succeeding Haj. The numbers leaving Jeddah are always rather less than those that arrived there. Some pilgrims have died in the Hedjaz; others have gone from Mecca overland to Medina and return thence to Yanbo (though this group is compensated by another group of pilgrims, who follow the reverse route, landing at Yanbo and leaving the Hedjaz by Jeddah); and some have settled in Mecca for a year or two or even for life.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

Degree Day, which was held on Saturday last, terminated the work of the summer term, which has been even more than usually extensive and successful. The Degree Congregation was held in the town-hall and fortunately the weather was fine during the passage of the procession from the University tuberculosis of the udder. No one can deny that such a system of control is desirable, the only debateable question being whether such control should be administered by the County Council as the central authority or by the local sanitary authorities. Meantime, the President of the Local Government Board has announced his intention of introducing a national Bill on the subject. Ultimately the Council decided to adopt an amendment, moved by Mr. Felix Cassel, that general legislation affecting the whole country and more effective administration are necessary for the purpose of securing a purer and more wholesome supply of milk and that representations to that effect should be made to the President of the Local Government Board and that it be referred to the public health and Parliamentary committees to give effect to this proposal. Further, the public health committee was instructed to report in detail as to any legislation which it may consider necessary for the purpose of securing a pure and wholesome milk-supply for London in particular pending, in addition to, general legislation after conferring with, or herwise ascertaining the views of, the metropolitan borough uncils and the corporation. The amendment was adopted a substantive motion and it was further agreed that wers should be sought to enable sanitary authorities in ondon to register cowkeepers, dairymen, or purveyors of ilk or to remove them from the register in the event of eir premises being found unsuitable for the sale of milk.

[3] THE LANCET, Feb. 16th, 1907, p. 464.

A WINTRY JUNE.

A very unsatisfactory May has been followed by a June hat was not only disappointing but actually miserable. The north-easterly and easterly winds of the former month did occasionally allow the thermometer to rise to the normal or even above it, but the south-westerly and westerly winds which largely predominated during June scarcely ever permitted the temperature to reach its average level during the afternoon, and generally kept it at some degrees below that point. During June of 1906, a by no means warm month, the shaded thermometer in London rose to 70° F. or above on 18 different days, but only once during last month did the metropolis experience the warmth of 70°. Such a continued low temperature may have occurred during some Junes of the past century, but statistics prove that no June of the last 35 years has given such monotonously cool weather, although several have been wetter and some have afforded less sunshine. As many of the nights, however, were rather mild the mean temperature for the month was not nearly so much below the average as the persistent cold days would cause to be supposed. In London the mean warmth of the nights was 51·2°, which is 0·9° above the average, but the mean temperature of the afternoons was only 63·6°, a figure as much as 5·7° below the normal. The low temperature was in a large measure the result of the cloudy and overcast sky but that it was not entirely due to the absence of sunshine is proved by the fact that on days when the sky chanced to be practically cloudless the maximum temperature readings were still low. On the 16th Westminster enjoyed continuous sunshine, a total duration of nearly 14 hours being recorded, and yet the highest point attained by the screened thermometer was only 63°, more than 6° below the average, while the solitary maximum above 70° (on the 9th), was reached with about half the amount of sunshine. A similar lack of seasonable warmth during almost constant sunshine occurred on several days both in the metropolis and over the kingdom generally. Below will be found the aggregate duration of sunshine recorded by the Campbell-Stokes burning instrument for June both of this and last year, together with the differences from the average. The figures show that, considered generally, the minus value of last month was greater than the plus value of the sunny places on the south coast and others in the south-east an south-west had more than two hours per day less than th average duration. The brightest spot was Sandown, Isle Wight, for which place there is unfortunately no trus worthy average, while the places with the least divergen from the known average were Margate, Blackpool, an London (Westminster). Some of the coastal resorts we subject to attacks of sea-fog, and the abnormally sma number of hours recorded at Aberystwyth, little more th three per day, was to some extent due to that unwelcom phenomenon.

A CASE OF ANNUALLY RECURRING LARYNG SPASM.

A peculiar case of temporary laryngeal spasm, recu annually at about the same time, is recorded by D Hajek in the *Wiener Medizinische Wochenschri* March 30th. The patient came under observation fi Feb. 17th, 1898, complaining of great difficulty in b ing of four days' duration. An adenoma of consid size was found in the left lobe of the thyroid Laryngoscopic examination was very difficult owing urgent dyspnœa. The patient was kept in hospital a goitre was removed, but the dyspnœa persisted for ab days afterwards. During the next two years no further t was experienced, but in February, 1901, sudden and dyspnœa developed of so severe a character that trache was performed. Three weeks later the cannula was rem the breathing was quite natural, and on laryngo examination both trachea and larynx appeared norma February, 1902, another attack of dyspnœa developed, until the middle of April, but of less severe charac that no medical assistance was sought by the patient. that time similar attacks have occurred each year, beg at about the middle of February and lasting until the of April. The dyspnœa is constant during this perio day and night and practically without any remissions apparently not influenced by any medicinal treatment attack commenced this year on Feb. 4th. The patie observed to be dyspnœic, with stridorous breathing cyanotic appearance of the skin and mucous mem [illegible] examination the vocal cords were

seriously affect the supply. The water is supplied by the river Vyrnwy.

Presentation to Mr. James Taylor of Chester.

In the council chamber of the Chester town-hall on July 4th a presentation of suitable gifts, subscribed for by the people of Chester, to Mr. James Taylor, F.R.C.S. Eng., took place on the occasion of his retirement from the post of honorary surgeon to the Chester Infirmary. Mr. Taylor had been connected with the infirmary for 40 years, first as house-surgeon and afterwards as honorary surgeon. The Mayor of Chester presided over a large and representative gathering. The honorary secretary announced that the amount of subscriptions was £448 8*s*. 6*d*., and the expenditure £249 5*s*. 4*d*. The mayor asked Mr. Taylor's acceptance of an illuminated address, which read as follows:—

To JAMES TAYLOR, ESQ., F.R.C.S., J.P.

DEAR SIR,—The occasion of your retirement from the position of senior honorary surgeon to the Chester Infirmary is an opportune time in which to bear public testimony to the exceptional services you have rendered to this city and neighbourhood during the last 40 years. All that period you have been connected with the infirmary as house surgeon, then honorary surgeon, and ultimately senior honorary surgeon, and we fully recognise that you have partaken in so auspicious a degree in all the works and efforts that have been undertaken to promote the usefulness of that valuable institution since 1868. It is absolutely accurate to say that your services in this direction have been unique. Many of us are members of the honourable profession which you so greatly adorn by your widely acknowledged skill, your cultivated ability, and your abounding labours. Many of us are numbered among the great company of the grateful patients, and all of us are comprised in the wide circle of your friends and admirers. We beg to ask you to accept this clock and candelabra, illuminated address, and cheque as evidence of our affection and best wishes. We earnestly trust you may be long spared to pursue your useful and beneficent course, and that you, Mrs. Taylor, and your family may be abundantly blessed.

Yours truly,
JOHN JONES (Mayor),
EDWARD EVANS LLOYD (Chairman of the Board of Management of the Chester Infirmary,
G. WRIGHT, M.D. (President of the Chester Medical Society),
JOHN ROBERTS, M.D. (Honorary Treasurer),
A. G. HAMILTON, M.D. (Honorary Secretary).

Mr. J. R. Thomson, on behalf of the Chester Infirmary management committee, presented Mr. Taylor with a clock and candelabra and Mrs. Taylor was presented on behalf of the subscribers with a silver tea and coffee service. The fourth presentation, consisting of a cheque for £199 10*s*. 8*d*., was made to Mr. Taylor by his old friend and fellow student Dr. John Roberts. Mr. Taylor, who received quite an ovation, expressed his thanks in suitable and feeling terms.

Opening of the New Infirmary at the Clatterbridge Workhouse.

The extensive buildings and improvements carried out at the Clatterbridge workhouse were formally opened last week. The new infirmary affords accommodation for 46 patients, having four large wards with ten beds in each and six separate wards. The brick walls have high dadoes of glazed tiles and the floors are of polished wood. The whole premises are admirable as far as ventilation and cleanliness could make them. Besides the wards there are day rooms and wide airy balconies. The new infirmary is connected with the older building by means of a covered way. The nurses' home and laundry are also thoroughly up-to-date.

July 9th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Midwives in Swansea.

THE Swansea corporation, as the supervising authority under the Midwives Act, has appointed a woman inspector of midwives, and during the few months she has been in office a great improvement is said to have taken place in the methods and equipment of the registered but uncertificated midwives who practise in the town. Of the 88 midwives who are on the Swansea register only nine hold certificates from institutions or societies recognised by the Central Midwives Board. The inspector of midwives, jointly with the woman sanitary inspector employed by the corporation, visits the homes of newly born children in Swansea to ascertain the conditions of their feeding and to render advisory help where needed. There would appear to be plenty of work for these two officials, for the infantile mortality rate in Swansea has averaged for many years 160 per 1000 births. In the year 1906, of the 501 deaths of children under one year of age, as many as 141 died before reaching the age of one month, while in some parts of the town more than one-third of the deaths under one year of age occurred before the end of one month.

Newport Port Sanitary Authority.

In his annual report to the Newport (Mon.) Port Sanitary Authority the medical officer of health (Dr. J. Howard-Jones) draws attention to the unsatisfactory accommodation provided for the crew in many of the new British ships. Although vessels are now built of greater tonnage than formerly, inadequate provision is made for the needs of the crew in order that as large an amount of cargo may be carried as possible. After the vessels have been passed by the Board of Trade and arrive at a British port during a voyage they come under the notice of the port sanitary authority and it is not an uncommon occurrence, Dr. Howard-Jones declares, for structural alterations to be insisted upon in order to remedy nuisances quite soon after the vessel has been passed by the Board of Trade. This action is naturally a source of annoyance and expense to the owners and he suggests that there should be some recognised responsible authority whose duty it would be to make definite regulations, when better accommodation for the crew would frequently be provided without any extra cost.

A Low Birth-rate and Plumbo-solvent Water.

The birth-rate in Pontypridd has always been high and during the past few years the steady fall in the birth-rate which has been such a noticeable feature in other parts of the country has been entirely absent from the Pontypridd records. The reverse, indeed, has been the case for during the five years 1901–05 the Pontypridd birth-rate averaged 37·1 per 1000, while in the preceding five years it averaged 30·1 per 1000. In 1905 it was 36 per 1000, and in 1906 there was a sudden drop to 29·7 per 1000. In his annual report the medical officer of health (Mr. Howard Davies) says that it is difficult to say how far this low birth-rate was prejudicially affected by the injurious influences of the public water-supply. Examinations of the water which were made at different times during the year revealed the presence of one-fourteenth of a grain of lead per gallon. Mr. Davies urges that steps should be taken to counteract this plumbo-solvent action of the water which is obtained from high moorlands situated some 12 or 14 miles from Pontypridd.

Presentation to Dr. George Crowe.

The members of the Worcestershire and Herefordshire branch of the British Medical Association entertained Dr. George W. Crowe of Worcester at a dinner at Malvern on June 27th. The occasion was marked by the presentation to Dr. Crowe of a piece of plate by Mr. T. Bates on behalf of the members of the branch. Dr. Crowe was the first secretary of the branch upon its formation in the year 1880 and was continuously re-elected each year until 1906. He represented the branch upon the council of the Association from 1884 until two years ago when owing to the alteration in the constitution the representation upon the council was linked with that of Gloucestershire.

Winsley Sanatorium.

The annual meeting of the subscribers to the Winsley Sanatorium was held on July 3rd under the presidency of Dr. Lionel A. Weatherly. The medical report was satisfactory and the financial statement showed that the adverse balance on the year was £180, compared with an adverse balance of £650 on the previous year.

A Portrait of Dr. John Beddoe.

On July 5th the Right Hon. Lewis Fry formally presented to the city of Bristol a portrait of Dr. John Beddoe, who formerly practised at Clifton and now lives in retirement at Bradford-on-Avon (Wilts). The portrait was painted by Miss E. B. Warn and was purchased by subscription; it will be placed in the art gallery of the city. The frame of the painting has the following inscription: "John Beddoe, M.D., F.R.S., by Miss E. B. Warn, presented by some of his friends, 1907." Mr. Fry, in the course of his speech, alluded to the distinguished career and high scientific attainments of Dr. Beddoe, who they were all proud to think of as a Bristolian. Dr. Beddoe made an interesting little speech, in which he said that he had striven to do his duty for the city and hoped that he had not altogether failed.

July 9th.

good service in calling attention to the matter. He concluded a fighting speech by again asserting that he was concerned with the efficiency of life and not merely with a useless longevity and that the maintenance of the vitality and manhood of the nation is the true aim of medicine. His last word was for the surgeons whose very existence he ascribes to the inefficiency of true preventive medicine. Whatever view may be taken of Sir James Barr's opinions there will be few people who will regret that he had the courage of their free expression before a mixed audience, for they cannot fail to have set his hearers thinking deeply about a subject of national import.

EPSOM COLLEGE.

FOUNDERS' day at Epsom College will be held this year on the afternoon of July 27th, when the distribution of prizes will also take place. A service will be held in the school chapel at 2.45 P.M., and the new east window will be unveiled by the treasurer of the College, Mr. Henry Morris, himself an old Epsomian. The window, which has been erected by old Epsomians and friends of the school, will be dedicated by Dr. Furneaux, the Dean of Winchester. The Dean of Winchester will also distribute the chief prizes and will deliver an address. A parade of the cadet corps will take place during the afternoon.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN London during the month of June there were 17 cases of cerebro-spinal meningitis notified, four of them belonging to Stepney, two to Poplar, and one to each of 11 other boroughs. A death from the disease has also occurred in Nottingham, being the fourth fatal case in that city. In Scotland during the week ended July 6th there were ten deaths from this cause registered in Glasgow, three in Edinburgh, and three in Leith. In Glasgow the weekly report issued on July 5th showed that there were at that time 74 cases under treatment. In Belfast during the week ended July 6th there were five deaths registered as being due to this cause.

SUNDAY LABOUR.[1]

THE Sunday question is not an easy one to solve and, as might be expected, therefore, the literature dealing with it is not small. From "Seven Days' Hard Labour" we learn that in the British Museum the books or issues of various kinds dealing with the subject are nearly 200 in number, in the Bodleian Library at Oxford 169, in the Advocate's Library at Edinburgh 280, in the Royal Library at Berlin 215, and in the Congress Library at Washington 125. The present little book in question is a plea for a weekly rest day Act of Parliament for all classes and *consists* of a series of chapters pointing out the evil effects on the body and higher psychic functions of Sunday labour. One chapter is written in collaboration with Dr. Henry Shackleton and the arguments in the book are supported by men of authority, medical and clerical, of course, but also among all classes whose opinions carry weight. The work of our police service and omnibus and tramway men is dealt with, Sunday on the continent is discussed, the legislation on the subject is described, and the hygienic aspects of the question are pointed out. There can be no doubt that from many causes Sunday is becoming more and more a day of pleasure, with the necessary sequel that there is an increasing demand for Sunday labour. But no legislation is likely to restore to us the position which Sunday once held as a day of rest until some alteration takes place in our social and economic conditions. So far as the working classes are concerned, and it is principally in their interests that the book is written, the need for some change of occupation is the primary factor which causes them to seek forms of amusement on Sunday which do not tend to the best results, while increased work is entailed on other members of their class. Excursions by overcrowded trains or visits to concert rooms where the air is of necessity vitiated, for example, are not ideal methods of counterbalancing the effects of the week's toil but the laws of nature demand reaction which might take a worse form. We might as well try to ameliorate social and economic evils by prohibiting the use or invention of machinery as to interfere with the Sunday question by legislation. In both cases the remedy lies in the direction of further opportunities for relaxation during the weekdays and as the public become more and more educated in matters which concern the health of the individual and of the community and recognise the fact that proper rest and recreation during the working days lead in the long run to better work and the general good of all classes, so will the tendency to make Sunday the least restful of days lessen. It is only by education that true reform in this matter will be brought about. "Seven Days' Hard Labour" should do something to help a cause which has our full sympathy.

A NEW RADIO-ACTIVE SUBSTANCE.

IF the announcement from the School of Medicine at Rochfort this week is true that a substance has been prepared which shows the same radio-activity as does that of radium bromide, a very considerable impetus will be given to the study of radio-active phenomena. It is said that the substance is uranyl-molybdate, and judging from its constitution there should be no difficulty in preparing it or any trouble about finding plenty of materials, for uranium and molybdenum are fairly abundant elements. The molybdate is formed by adding ammonium molybdate to uranyl nitrate when a white amorphous powder separates. This is dried in the dark and apparently must be kept there as it is unstable. Report says that it gives radio-active effects which are practically as intense as those given by radium. Though costly—namely, about £22 per ounce—the price is not so enormous as is that of radium which has reached many thousand pounds for the same quantity. The further developments of this discovery, made by quite a young student named Andre Luncien, will be awaited with interest.

THE CHILDREN'S HOLIDAY.

THERE are some things of which it is difficult to appraise the value. One of them is the smile of a child and that smile, when brought about by a change from impure air and sordid surroundings to the pure air and beauties of the country, is enhanced considerably in value. Year after year we plead on behalf of the many societies whose objects are the provision of annual holidays for the poor children who live in our slums and alleys. Alas, that such places should still remain with us, but while they exist it is the duty of everyone who is able to assist these societies in their benevolent and truly national work. For, as we have frequently pointed out, it is not only the individual child who receives benefit but also the community in general. The Bishop of Stepney has issued an appeal to the press on behalf of the Children's Fresh Air Mission, a society which chiefly deals with the 3000 children in the overcrowded streets of Clerkenwell, Holborn, and St. Luke's, and to give these children the holiday which they so urgently need at least £1500 in addition to the sums already received are required. For the sum of 10*s.* one of these children will receive a fortnight's holiday amidst surroundings which can only be described as elysian, as compared with the environment had been notified, as against 14 in the previous week, and for the week ended Saturday, June 29th, six deaths were reported, as against 20 in the week ended June 22nd. Of 87 cases in the fever hospital at Purdysburn 37 were on July 4th suffering from cerebro-spinal meningitis.

---

[1] Seven Days' Hard Labour: The Bitter Cry of the Sunday-less. By [illegible] Hygienic League. Price 6d.

The Mater Infirmorum Hospital, Belfast.

As a result of the Saturday collection (June 29th) a total of £1142 (including £120 handed in at the hospital) was obtained, a sum larger than that of last year.

Cowan Heron Cottage Hospital, Dromore.

At the seventh annual meeting of the governors and subscribers held on July 4th, references having been made to the gratifying results of the year's working and to the increase in last year's subscriptions, Mr. W. O. Heron, D.L., who presided, stated that he was anxious to assist still further the good work being done and to that end was at present having plans prepared for the extension of the hospital buildings by the erection of two convalescent wards.

The Belfast Asylum.

At present there are 678 patients in the Belfast Asylum, 398 at Purdysburn new asylum, and at the Ballymena annexe 62. At a meeting of the asylum committee held on July 8th it was decided, at the request of one of the members, to make out a list of the paying patients.

July 9th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Monument to Professor Brouardel.

A VERY influential committee has been formed for the purpose of erecting in Paris a monument to Professor Brouardel who died about a year ago and an obituary notice of whom appeared in THE LANCET of August 11th, 1906. Professor Brouardel was for many years a representative figure in the medical profession in France and his numerous writings, as well as his occupancy of important positions in international congresses, made his name universally known in medical circles. The committee has the patronage of the President of the Republic, the Minister of the Interior, and the Minister of Public Instruction. The President of the committee is M. E. Loubet and the list of vice-presidents contains more than a hundred names of persons eminent both in science and in public life. Subscriptions to the fund are received by MM. J. B. Baillière et Fils, 19, Rue Hautefeuille, Paris.

Proposed Non-medical Control of Medical and Surgical Work in the Paris Hospitals.

The general council of the Sociétés Médicales d'Arrondissement de Paris et de la Seine has been recently considering a somewhat unusual question. The council had heard that M. Soller had offered to provide a fund for the creation of special departments which, though under non-medical direction, would have control over the medical and surgical work of the Paris hospitals. The council was of opinion that scientific knowledge could not be usefully applied in medical questions except by persons who had received a medical education, and in the interests of the patients it was necessary that the physicians and surgeons should be at liberty to employ whatever treatment they conscientiously believed to be best. A medical man was legally responsible for any imprudent or culpable act (*faute lourde*) committed in his professional work. The council was therefore strongly opposed to the suggested creation of a controlling authority composed of persons who had not received a medical training.

The Death of the Princess Henrietta, Daughter of Charles I. of England.

In a paper read at a recent meeting of the Société de Médecine de Paris Professor Pozzi discussed some very interesting questions connected with the last illness of the Princess Henrietta, daughter of King Charles I. of England and wife of the Duke of Orleans. He said that the principal explanations which had been suggested were poison or acute peritonitis which might have proceeded either from perforation of a gastric ulcer or from perforation of a gangrenous appendix. Professor Pozzi, however, from an examination of the clinical and anatomical references in contemporary accounts of the case, has come to the conclusion that the death of the Princess in nine hours was due to profuse internal hæmorrhage caused by the rupture of an extra-uterine pregnancy in the first or second month. He drew attention to the complete agreement of the classical symptoms of this condition with those which were observed in the Princess's illness. He said that the absence of vomiting was fatal to the hypotheses of poisoning or peritonitis. As the lower part of the abdomen was not examined at the necropsy out of respect for the rank of the deceased, it was not surprising that pelvic hæmorrhage was overlooked.

Appointments.

At a meeting of the Academy of Medicine held on July 2nd M. Bar was appointed a member in the section of obstetrics in succession to the late Professor Budin. The council of the Faculty of Medicine have made the following appointments to vacant chairs: M. Bar to the chair of clinical obstetrics, in succession to Professor Budin; M. Quénu to the chair of *médecine opératoire*, in succession to Professor Terrier; and M. Prenant of Nancy to the chair of histology, in succession to M. Mathias Duval.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Researches on Cancer.

Professor von Leyden and Dr. Bergell, writing to the *Deutsche Medizinische Wochenschrift*, have made an interesting communication on cancer. They said that the endeavours to destroy cancer by certain ferments, such as pancreatin, were of no practical use, as by injections of this substance not only cancerous but also healthy tissue was attacked. During the course of their experiments they also examined other ferments of animal origin and in the liver they found one which acted on peptones which were resistant even against pancreatin. Injections of small quantities of this ferment into malignant growths produced a quickly progressive necrosis of the tissue. The naked-eye appearances consisted in softening and liquefaction of the tissue; microscopically it was seen that necrosis had occurred and that the nuclei of the cells had lost their staining capacity. Caseous degeneration was not observed, except in malignant growths occurring in mice. The principal feature of the injection was the selection made by the ferment between cancerous and healthy tissue, the necrosis being limited only to the malignant growth. It was not yet possible to use this procedure for therapeutic purposes, but the discovery was very important from a theoretical point of view. There was a marked difference between pancreatin and the liver ferment. Pancreatin digested the isolated albuminous substance of cancer and also the growth in the test-tube but produced only a small circumscribed solvent effect in the living growth. The liver ferment acted neither on the isolated albuminous constituents of cancer nor on the growth in a test-tube, but it had an extremely powerful action on the living growth, on carcinoma as well as on sarcoma. This fact led to the conclusion that the normal organism contained a specific hydrolytic ferment, deficiency of which caused the growth to increase.

The Treatment of Syphilis by Atoxyl.

Professor Lassar has given in the *Berliner Klinische Wochenschrift* some details of the treatment of syphilis by atoxyl. He said that the efficacy of atoxyl against sleeping sickness, a disease caused by a protozoon, led to the conclusion that this remedy might be equally efficacious against other protozoal diseases. As the protozoal nature of syphilis has been acknowledged since the discovery of the spirochæta pallida by the late Dr. Schaudinn, atoxyl was tried as a remedy against this disease. Following the method recommended by Dr. Salmon of Paris, 0·5 gramme of atoxyl in a solution of 10 per cent. strength was injected every second day, the result being that the symptoms of recent syphilis disappeared. Undesirable complications, however, were caused by the cumulative action of the drug, especially disturbance of the patient's general health, but this ceased at once when the administration of atoxyl was stopped. A smaller dose was therefore used by Professor Lassar with excellent results in 25 cases of both recent and long-standing syphilis. Primary ulcers healed, papules underwent a regressive metamorphosis, annular forms of the exanthem faded, and

DECENNIAL SUPPLEMENT FOR 1891–1900 TO THE SIXTY-FIFTH ANNUAL REPORT OF THE REGISTRAR-GENERAL.

PART II.

CONTINUING our notice of this report, certain portions of which were considered in *THE LANCET* of June 29th, we observe that the progress of sanitation is seriously impeded by reason of the overlapping and confusion of administrative areas which still unfortunately persist. There are now in this country about a dozen urban sanitary areas, including three county boroughs, which extend not only into more than one registration district but into more than one registration county as well. No organised attempt has hitherto been made to coördinate the Poor-law unions—on which the system of registration districts is founded—and the urban and rural districts, which are the units of area for sanitary purposes. Such coördination is doubtless hindered by practical difficulties, but its advantages are so great and so obvious that Dr. Tatham rightly protests against indefinite delay in attempting to secure it.

Ever since the passing of the first Public Health Act a steady growth of public interest has been maintained in the cause of sanitary reform, the progress of which has doubtless been encouraged by the popular, though erroneous, belief that the reports of the Registrar-General furnish an accurate and sufficient measure of the health of every administrative area in England and Wales, as well as the means of testing the effect of works undertaken from time to time for the improvement of local sanitary conditions.

In his previous decennial supplement Dr. Tatham expressed regret that although since the year 1847 particulars of mortality had been published decennially with respect to the causes of death in each of more than 600 registration districts, nevertheless this elaborate series of tables could seldom be utilised for purposes of public health administration because of the overlapping of areas above referred to. At the end of the year 1906 the number of urban districts in England and Wales was 1166 and yet only 149 of these were co-extensive with the registration areas to which alone these statistics relate.

For the purpose of comparing English mortality in the urban with that in the rural districts for the decennial period 1881–90 the urban area was represented by the 78 largest towns and the rural area by the remainder of England and Wales, the death-rates in these areas being approximately corrected by the indirect method employed in the annual summary when the local death-rates at the several age-groups are not known. For the present report the mortality has been calculated on an improved method for every registration district and every registration county of England and Wales. In order to emphasise the great differences still obtaining between the mortality of the towns and that of the country a selection has been made from among the English and Welsh counties showing in one group the counties which are mainly urban in character, containing the chief centres of industry, and in another group the counties which are mainly rural in character—the latter group contrasting strongly in this respect with the former. As the urban area contains a population of 16,500,000 and the rural area a population of 4,250,000, we see that urban and rural England are fairly represented by the selections made. For these areas respectively the death-rates in 1891–1900 have been corrected for age differences of population, and the results of this correction are illustrated in a table inserted in the report. From this table we learn that while the crude (i.e., the uncorrected) death-rates show a difference of only 2·46 per 1000 as between the urban and rural areas, the corrected rates show a difference of not less than 5·46 per 1000.

That local differences of mortality are in some way related to varying degrees of density of population is matter of common knowledge. For the national statistics prove that the areas with the highest death-rates are, as a rule, the densely populated industrial centres, while the sparsely peopled rural districts show almost invariably the lowest death-rates. The late Dr. William Farr devised a formula showing approximately the relation subsisting in 1861–70 between density and mortality in the districts of England and Wales. But in these days the relations existing have become too complex to admit of expression by any known formula. That mortality does still increase as density increases is shown by tables in the report, but this increase may with much probability be accounted for by other factors directly due to excessive overcrowding rather than by increased density *per se*. In this connexion it may be mentioned that whilst the mean density of the English population rose from 471 persons to the square mile in 1881–90 to 525 persons in 1891–1900, the death-rate fell from 18·73 per 1000 living to 18·19 per 1000.

Recent statistics show that whilst in 1881–90 no English district had a corrected death rate below 12 per 1000, in the following decennium there were 27 districts in which the mortality fell below that limit. The number of districts with rates between 12 and 13 per 1000 rose from 33 in the former decennium to 112 in the latter. Altogether, in the first-mentioned period there were 417 districts, with 9,000,000 inhabitants, that had corrected death-rates below 17 per 1000, as against 461 districts, with 12,000,000 inhabitants, in the period last mentioned. At the opposite end of the scale there were in 1881–90 not fewer than 41 districts, containing 5,500,000 people, that experienced death-rates above 23 per 1000, whereas in 1891–1900 the number of districts thus heavily rated did not exceed 20.

The proportion of deaths registered as uncertified varies enormously in different parts of the country. In Herefordshire the proportion in 1891–1900 was 5·2 per cent. of the total deaths, and in North Wales it was 4·8 per cent. On the other hand, the percentage did not exceed one in Middlesex, Wiltshire, or Monmouthshire. In relation to this subject attention is drawn to the fact that in many cases inquests are held on the bodies of persons who had been actually under medical care at the time of death. Such deaths are placed under the head of "inquest cases," and are excluded from the list of deaths medically certified. In many instances medical evidence is undoubtedly given at the inquest; but except in cases where a necropsy has been made there are no means of ascertaining whether or not medical evidence has been given. The medical evidence concerning the cause of death is often obscured by the manner in which the verdicts of coroners' juries are worded and consequently this information is lost for purposes of vital statistics. It is much to be regretted, writes Dr. Tatham, that the trustworthiness of the national registers should be thus impaired, for a large share of the time of the Registrar-General's official staff is occupied in the endeavour to maintain the efficiency of registration.

In the year 1881 a useful system of confidential inquiry was established for ascertaining the true cause of death in the large number of instances in which the cause had been certified so vaguely as to be useless for purposes of classification. The gradually increasing work of the statistical department has hindered the full development of this system; nevertheless, in the decennium ended 1900 more than 39,000 answers were received to letters addressed to medical practitioners as compared with 22,000 in the preceding decennium. In this connexion Dr. Tatham very gratefully acknowledges a substantial improvement in recent years, both in the character of the original medical certificates examined by him and in the value of the replies to his inquiries respecting doubtful cases. As a result of these inquiries there were added to the total mortality from puerperal sepsis and accidents of childbirth 2050 deaths, of which 932 had originally been certified as from peritonitis, 510 as from pyæmia or septicæmia, 151 from metritis, 178 from pelvic cellulitis, and 117 from hæmorrhage, in all these instances without mention of the puerperal condition. The deaths from cancer or malignant disease were increased by 6252, of which 5255 had been returned as from tumour, 874 as from stricture of the œsophagus, 42 as from hæmorrhage, 30 as from dyspepsia, and 22 as from atrophy, whilst 70 had been indefinitely returned as from surgical diseases. The deaths from tuberculous diseases were increased by 1344, of which 717 had originally been certified as from tumour, 193 as from peritonitis, 124 as from atrophy, 52 as from pyæmia or septicæmia, and 36 as from surgical causes. It should be mentioned that with every one of the aforesaid letters of inquiry a circular is inclosed, containing a new list of diseases based on the recently issued nomenclature of the Royal College of Physicians of London, so that medical practitioners have ready at hand the latest official information respecting the classification of causes of death.

(To be concluded.)

weeks old both the mother and the child were inoculated with tuberculin as a diagnostic measure with a positive result. This is the youngest patient on record in whom the injection of tuberculin proved the presence of tuberculous material in the system. When the child was five months old a tuberculous manifestation called tuberculid appeared on the skin, so that the infection was now proved even clinically. The site of the diagnostic injection, which at the same time is used for therapeutic injection, is a small pale red papule about a quarter of an inch in diameter.

A Case of Complicated Cataract.

Professor Königstein showed at the same meeting a man who was suffering from cataract of the left eye and who had been sent to him from a distant country. The patient, whose right eye was very myopic, had six years ago sought relief for his cataract, but operation was refused on account of the perception of light being unsatisfactory. The vision subsequently improved a little, but he wished to be cured of his cataract. The appearance of the eye was very unusual and interesting. The entire anterior chamber was filled with glittering points, especially during lateral illumination, as if the cornea were studded with gold-dust. Most likely the reason of this remarkable phenomenon was to be found in very small particles of cholesterin lying in close apposition to Descemet's membrane and probably imbedded in the corneal parenchyma also. The pigmentation of these particles was due most likely to hæmoglobin. The formation of these bright points might be explained on the hypothesis that some time ago the capsule of the lens had burst and the substantia propria of the lens had undergone a regressive metamorphosis which produced the cholesterin. Bleeding often occurred in degenerated eyes and thus the pigmentation was easily accounted for.

The Collection and Disposal of Household Refuse.

The question of dealing with the household refuse produced in a city of 2,000,000 inhabitants has for some time been engaging attention and the following results have been obtained from the experiments conducted by the municipal authorities. As regards the disposal of the dry material collected in the dustbins, the method giving the best result has been combustion. The refuse is collected by carts provided with special receptacles. All the dustbins are covered square boxes of a uniform shape and size, about 75 centimetres long, 50 centimetres high, and 50 centimetres wide. These boxes are pushed into the receptacle of the car, which is then closed by a lid, and the box is uncovered and emptied by turning a handle without any dust escaping into the street. The refuse is then conveyed to the "combustorium," where it is burned, except such portions as can be used otherwise. Old metal, tin ware, and glass are melted down in a special apparatus and used for industrial purposes, whilst the combustible material is used to generate steam for driving two dynamos for lighting the building. As yet these trials have been conducted on a small scale, but if the system is approved of and the refuse collected from the whole city is treated in this way the amount of energy obtained will be very considerable. The treatment of wet refuse, especially of an organic nature, has not hitherto yielded satisfactory results, and another series of experiments with this material has been instituted in the hope of using it as manure. The cost of refuse disposal on the system above described is very small and the process is even expected to be profitable for the municipality if conducted on a large scale, whilst it is undoubtedly the best way from the standpoint of hygiene and medicine. In particular, the method of collecting refuse without scattering dust is sure to be imitated by many corporations, whilst a fruitful source of contamination of the air, especially during the busiest hours of the day, is thus easily done away with.

Professor Chrobak's Resignation.

Professor Chrobak, the celebrated gynæcologist, some time ago announced his intention of retiring from his academic position, but illness has unfortunately compelled him to hasten the preliminary stages and a few days ago, when the lectures of the summer term were concluded, he took leave of his pupils and his clinic. A large number of students, former and present assistants, and friends of the professor assembled in the lecture room of the gynæcological clinic to pay their respects. Representatives of the students and of the clinical staff bade the eminent teacher farewell and dwelt in their speeches on the great influence which he exercised on the minds of his surgical contemporaries. His conservative mind, his promptitude in action, his precision, and his interest in both patients and pupils were sufficient to impress his personality on the memory of every one of his friends. In his reply Professor Chrobak confessed that his one ruling principle which he wished to leave to his pupils was, *Primum non nocere* (first of all not to do any harm). This maxim ought to be kept in mind by every member of the profession, and especially by the obstetric surgeon, who was so often called on to assist nature in a physiological, not a pathological, condition. He admitted that he found it very hard to relinquish his post, to which he had devoted so many years, but failing health now left him no option. Meanwhile, until the successor of Professor Chrobak takes over the new clinic in the newly built General Hospital Dr. Peham, the last assistant of Professor Chrobak, will temporarily carry on all his official duties, including the examination of the candidates at the so-called "rigorosum" or severe final examination for the degree of M.D. This "interregnum" will continue for at least a year, as Professor von Rosthorn is not expected to relinquish his present position before the summer of 1908

A Case of Malformation of the Skull and Clavicles.

A rare combination of rudimentary clavicles and anomalies in the conformation of the skull, described by Santon and Pierre Marie under the name of "*dysostose-cléido crânienne*," was shown by Dr. Fuchs at a recent meeting of the Neurological Society. The patient was a man, 23 years old, and was being treated for catarrh of the eyes, when the remarkable conformation of his skull attracted attention. He was one of twins, but no other member of the family was abnormally developed; on the contrary, they were all tall and well built, whilst he was less that 5 feet (148 centimetres) in height. His head was disproportionally large, measuring 24 inches in circumference, 16 inches in length, and 17 inches in breadth. The fontanelles and the sutures were still open. His clavicles were represented only by short floating, moveable, osseous bands, about two inches long, so that his shoulders could be brought together to meet in front. The upper and lower jaws were also rudimentary, containing only ten teeth in all. X-ray photographs showed that the rest of the skeleton presented no abnormal formation. The man's intellectual and psychical faculties were not impaired and he was better educated than a person of his station in life usually was. His infraspinatus muscles were in a condition of aplasia so that his shoulder blades were more visible than normal.

July 8th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply of Constantinople.

CONSTANTINOPLE is supplied with drinkable water from several different reservoirs, some of which are of very large dimensions. These reservoirs are commonly called "the bends," and the chief and most important among them are seven in number. The best known are the "bends" of Topouzlou, Validé-Sultane, Sultan-Mahmoud, Belgrad, Aivala, and Tonourlou. The first two, constructed two centuries ago, supply with water the European quarter Pera and its adjoining districts. The numerous fountains of Stamboul receive their water from the other four reservoirs. The largest "bend" is that near the village of Belgrad, several hours distant from the metropolis. It receives water from three different rivers and requires one hour and a half to be visited in all its length. It is situated in a most picturesque locality and forms in the spring and summer months a much-frequented and sought-after place for excursions. Nearer to the capital are the reservoirs of Validé-Sultane, Sultan-Mahmoud, and Topouzlou. The first is 114 years old and is very solidly built. Its height is over ten metres. The thickness of its walls is seven metres. It bears an inscription giving the name of the foundress and reproduces in chronograms the year of the *hegira* 1211. The most modern "bend" is that constructed by Sultan-Mahmoud (the "Reformer"), who reigned from 1808 till 1839. It is considerably larger than the former reservoir, its height measuring about 16 metres. The waters of the "bends" come out through numerous taps, pass through elaborate wire gratings, traverse an aqueduct, and are then

THE PAYMENT OF MEDICAL MEN SUMMONED BY MIDWIVES TO THEIR ASSISTANCE.

THE attention of medical men has frequently been called o the grave defect in the working of the Midwives Act f 1902, caused by the fact that although a midwife is ound by the Act to summon a medical man to take harge of a case of difficult labour, yet no provision is ade under the Act for the payment of his services. In ases of poverty, where the patient is entitled to charitable elief, the difficulty has not been so serious, but in many nstances medical men have attended knowing full vell that no fee would be recoverable and have given heir services as charity with the knowledge that if they ailed to do so they would risk public censure for heartless-ess. Certain boroughs, such as Liverpool and Cardiff, ave adopted schemes by which, in some circumstances, the orough became responsible for the fees due; in this they ave more freedom than the county councils the accounts f which are under strict central control. The latter have nly been able to suggest that medical men should seek to ecover from local boards of guardians, a very feeble uarantee of repayment. The latest council to take action s that of the borough of St. Helens which has adopted he scheme which we print below, the power for which it inds under Section 133 of the Public Health Act :—

The council of the county borough of St. Helens is prepared to make ertain payments to medical practitioners called in under Section E 18 nd E 19 of the rules framed by the Central Midwives Board, under ection 3, I., of the Midwives Act, 1902. (2 Edw. 7.c.17.) These payments will be made only on the written application of the medical ractitioner after consideration and investigation by the health committee of the council. In determining which cases shall come under his scheme the health committee will take into consideration: 1. ature of case. 2. Inability of medical man to recover his fee.

1. *Nature of the case.*—The expenses of medical attendance will be aid only when there is great urgency, and under Section E the cases f urgency will include: 19 (1) The whole sub-section; 19 (2,b when here is loss of blood; 19 (3. the whole sub-section; 19 (4) secondary ost-partum hæmorrhage; 19 (5) dangerous feebleness of the child; but ll other cases when there is undoubted urgency and danger to either nother or child shall be included whether mentioned in the foregoing ist or not.

2. *Inability of medical man to recover his fee.*—The medical man is equired to take reasonable means to secure his fee before applying to he health committee. The fee will be paid only on the written eclaration of the medical attendant that he has been unable to obtain he whole or any part of it from the patient, and shall be wholly or artly repayable by the medical attendant to the council if ubsequently whole or part payment be made by or on behalf of the atient. The medical attendant shall also be required to give a escription of the case, and the treatment adopted, on a prescribed orm. (Copy attached.) The fee for attendance on all cases of urgency nd danger to either the mother or the child shall be on the scale of s. for a visit, or £1 1s. when operative interference is required and has een carried out. The fees are not cumulative and the fee in any one ase shall not exceed 5s. when operative interference is not required nd £1 1s. when an operation has been required and carried out. Any laim for an additional fee must be made in writing, and will be onsidered by the health committee on its merits. Nothing in this cheme shall be held to bind the health committee or the council to pay the fees of any medical attendant in cases which they, after nvestigation, shall for any reason whatsoever deem unsuitable. The health committee reserve to themselves the right of withdrawing or mending the scheme.

W. H. ANDREW, Town Clerk.

Town Hall, St. Helens, June 5th, 1907.

The following is the form that must be filled up and returned to the council by the medical man who makes the claim.

THE MIDWIVES ACT, 1902.

To the Health Committee of the County Borough of St. Helens.

I hereby certify that on..............................

at.............. P.M. / A.M. I was called in at the instance of a midwife ....

to attend.............................. at ....

The reason given on the paper furnished by the midwife for calling me in was ....

The case was one of urgency and I found the following conditions requiring medical assistance :—..............................

....

The treatment which I adopted was briefly as follows :— ....

....

I hereby declare that I have failed to obtain my fee in whole or part for this attendance, and that I have taken reasonable means to secure it. I further undertake to refund to the council any payment made to me with respect to this attendance, should whole or part payment be made to me by or on behalf of the patient.

....

Address..............................

Date..............................

This form duly filled up and signed by the medical practitioner must be sent to the Medical Officer of Health, Town Hall, St. Helens, within six months of the date of the attendance.

THE HAMPSTEAD GENERAL HOSPITAL.

RECENT events in connexion with the constitution of the staff at the Hampstead General Hospital have led to a situation that threatens to become almost an *impasse* and as they involve principles of the greatest importance to all suburban hospitals and to medical men a short statement of the facts will be useful.

The Hampstead Hospital was founded in 1882 as a small nursing institute, with the title of the Hampstead Home Hospital. The late Dr. Heath Strange associated with himself several local medical men as a staff and until his recent death took the greatest interest in the affairs of the institution. There were no free beds until 1893, when a few were added, and three years later an out-patient department was started which was the first step that brought on the institution the criticism of practitioners in the neighbourhood who were not on the staff. In 1905 the hospital was moved into a fine new building that had been erected on Haverstock-hill with 64 beds but the move had not the cordial support of the local profession, many of the members of which consider that Hampstead does not require so large a hospital. In spite of this feeling the council of the hospital—as the board of management is styled—during 1906 proceeded with the erection of two new wings, which was made possible by a donation of £20,000 from Sir Henry Harben, and one of £5000 from King Edward's Hospital Fund for London, and new out-patient buildings were also erected. The hospital is administered by the council, on which all the six members of the medical staff have seats, although of course the lay representation has a strong majority. The staff consists of four medical officers and two assistant medical officers, all of whom are local practitioners and make no claim to what is generally known as a purely "consultant" practice. It must be said at once that on all sides it is admitted that these gentlemen carry out their duties in an exceedingly efficient and skilful manner and the question at issue is one of principle entirely and not of personality. Up to the present time they have had exclusive charge of the free beds and the out-patients but have shared the right of treating their own private cases in the dozen or so paying beds with any other practitioner who chooses to apply for such a bed in which to treat a private case, preference being given to patients coming from Hampstead, Highgate, Hendon, or the neighbourhood. The new wings when open will give a total accommodation of about 110 beds and the number of paying beds will be increased.

It is about the free beds that the chief trouble is centred. When the hospital was moved to its present site a good deal of local feeling arose on several counts; one was that the staff derived an undue local prestige from their official position, but the chief trouble was the hostility of the local profession against the out-patient department. During May, 1906, the local branch of the British Medical Association convened a meeting of neighbouring practitioners who carried the following motions and a committee was formed to promote their enforcement :—

1. That an out-patient department in Hampstead is unnecessary.
2. That the casualty department *be kept distinct from any other* department and that casualty patients, if not suitable for admission, be seen once, and thereon be referred to private practitioners, provident dispensaries, or Poor-law authorities.
3. That there be greater facilities for general practitioners of the neighbourhood to attend in-patients.
4. That there should be a service *limit*, as well as an age *limit*, to appointments to the medical staff.
5. That the outside medical profession be adequately represented on the board.
6. That it is desirable, both in the interest of the district and of the hospital itself, that the Hampstead Hospital be carried on as a purely local institution, and not as a large general hospital, and that therefore an acting staff of consultants is not in accordance with the spirit of its constitution.

These were forwarded to the council of the hospital but they did not receive the support of the hospital staff and they cannot be said in themselves to have carried much weight. Neither can the indefinite expression of opinion in answer to a circular sent out by the council to the local profession asking for an expression of opinion on the constitution of the staff be said to have influenced the result materially. It will be seen that the last resolution deals with the introduction of a staff of consultants, and it is over that point that the present critical position has arisen; it is the point that makes the situation a test-case for

Obituary.

SIR WILLIAM HENRY BROADBENT, BART., K.C.V.O., M.D. LOND., F.R C.P. LOND., LL.D. EDIN. & ST. AND. & TORONTO, D.SC. LEEDS, F.R S.

COMMANDER OF THE LEGION OF HONOUR; PHYSICIAN IN ORDINARY TO H.M. THE KING AND H.R.H. THE PRINCE OF WALES; CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL, THE LONDON FEVER HOSPITAL, AND THE NEW HOSPITAL FOR WOMEN.

THE hand of death has been heavy in the ranks of the most honoured of the medical profession during this year. It has been our sad duty to chronicle recently the loss of Dr. Robert Barnes, Sir Joseph Fayrer, Sir William Gairdner, and Dr. E. H. Bennett, and now is added the no less painful task of writing the last record of another great and strong man whose influence made a deep mark on the practice of medicine during the nineteenth century—a mark that will remain indelible, for the subject of this memoir up to the illness that led to his death evinced the strongest and most practical interest in many of those beneficent movements for united national and professional action in the battle against disease that form such a hopeful feature of the present times. Sir William Broadbent well deserved the titular distinction that came to him as a direct result of the gratitude of his Sovereign no less than of his distinguished professional ability, but we may begin our review of his career by stating that in the minds of his many friends there will be uppermost just now not the long list of professional and official honours that he so worthily earned, but the remembrance of a kind, genial, upright gentleman of whom it may be said with literal accuracy that he was the friend of the fatherless and the afflicted. To all these friends, and in still greater degree to his immediate family, we offer on behalf of our readers the expression of our deep sympathy in their irreparable loss.

Sir William Broadbent was the son of John Broadbent of Longwood Edge, Huddersfield, where he was born on Jan. 23rd, 1835. He was educated at Huddersfield College, which institution he left at the age of 16, intending, in deference to his father's wishes, to embark on a business career. Commerce, however, was not congenial to his tastes, and being permitted to follow his bent, which was towards medicine, he proceeded to the Owens College, Manchester, subsequently entering the Royal School of Medicine in that town. His student career was a brilliant one, and this was all the more creditable to him because he had no great advantages at starting. It was then the days of apprenticeship and while a mere lad with very little money to spare, and working in the distracting surroundings of a general practice, he gained medals in materia medica, botany, and midwifery in 1855 and in the following year medals in anatomy, physiology, medicine, surgery, and operative surgery. With this record it is not surprising that he gained great distinctions further afield, carrying off the gold medals in chemistry and in anatomy and physiology at the University of London in the first M.B. examination, and in the final in 1858 graduating with first-class honours in medicine and the gold medal in obstetric medicine. Previously to his final examination in London he spent eight months in Paris studying medicine, and he maintained an active interest in French medical affairs until the end of his days. In 1858 he came to London and attached himself to St. Mary's Hospital, a connexion which had a very beneficial effect in shaping the fortunes of that institution, as all those who know the history of the hospital and its medical school will testify. He held the post of obstetric officer there and both then and for some time after showed a marked predilection for that branch of the profession; indeed, nine years later he contributed a paper in the Transactions of the Obstetrical Society of London.

He was, however, destined to turn to medicine for the main business of his life and this decision was, perhaps, due to the stimulating influence of Sibson, to whom he became house physician, and in whose wards he had the privilege of listening to clinical teaching which, at any rate in relation to diseases of the chest, was at that time not to be equalled in London. It is not surprising that a teacher who loved his subject to such an extent that he would spend half an hour listening to a murmur should in some way mould the mind of his brilliant junior, and Broadbent's subsequent work in diseases of the heart was well worthy of his distinguished master. Sibson's influence naturally also turned his thoughts to pathology, for no one was more zealous in correcting the speculations of the wards by the revelations of the post-mortem room; and in 1859 young Broadbent was appointed pathologist to the hospital. The following year he took his doctorate at the University of London and began his long teaching career of 36 years in the medical school of St. Mary's Hospital. The diversity of his scientific attainments is shown by the fact that he successively held the posts of lecturer in zoology, physiology, pathology, and medicine. He was also medical superintendent of St. Mary's Hospital for a time and in 1864 he was elected physician to out-patients at the same hospital. In 1861 he became a Member and in 1869 a *Fellow* of the Royal College of Physicians of London. He held office on the medical staffs of several other hospitals besides St. Mary's Hospital, being appointed successively out-patient physician to the Western General Dispensary, physician to the London Fever Hospital, and later to the New Hospital for Women. But it is with St. Mary's Hospital that his name will always be associated. For 17 years Broadbent held the post of lecturer at St. Mary's Hospital, first in conjunction with the late Dr. King Chambers, from 1871 to 1877, then alone until 1882, and finally in conjunction with Dr. W. B. Cheadle until 1888. Although his interest naturally embraced the whole of inner medicine at this time he turned his more particular attention to the study of diseases of the heart and of the nervous system. About 1870 he enunciated the hypothesis that gave him his chief prominence in the field of neurology in an article contributed to the *British and Foreign Medico-Chirurgical Review* on the Association of Nerve Nuclei, by which he sought to explain the immunity of the bilaterally associated muscles from paralysis in hemiplegia. The subject of aphasia also arrested his attention and from time to time he published some interesting theories in connexion with that very vexed matter. He maintained his interest in this subject until the end of his life, and one of his most recent publications had reference to the cerebral mechanism of speech production, in which he considered from an original point of view the phenomena of word-blindness, especially in relation to the education of children. In 1888 he resigned his lectureship in medicine to take up that in clinical medicine in his hospital, and his teaching in the wards will be remembered with gratitude by many of his former pupils. After his appointment to the staff of St. Mary's Hospital his own practice as a consultant began rapidly to increase, and it was soon evident that he was destined to attain to professional pre-eminence. In 1887 at the Royal College of Physicians of London he delivered the Croonian lectures on the pulse, and these addresses stamped him as an acute observer and original thinker. They formed the groundwork of a book which he published 13 years later on the same subject, a book that should become a classic as a record of what the unaided finger could appreciate before the days of the clinical employment of the sphygmomanometer. In 1884 he delivered before the Harveian Society a set of lectures on Prognosis in Valvular Disease of the Heart, and in 1891 when it fell to him to deliver the Lumleian lectures he chose for his subject "Prognosis in Structural Diseases of the Heart."

Writing in collaboration with his eldest son, Dr. John Broadbent, in 1896 Sir William Broadbent produced a book on heart disease which is unquestionably one of the best works that has been published on that subject. Although his collaborator has been chiefly responsible for the latest edition, Sir William Broadbent accepted full responsibility for the first, and the manner of his writing gives a good insight into his method of thought and teaching. It was above all things practical and such points of outstanding importance as prognosis and treatment received far more attention than abstruse speculations on doubtful problems in hæmo dynamics. Sir William Broadbent was content in dealing with any debateable matter to fix upon the explanation that most coincided with his own common sense, and with no more ado to pass on to something of greater clinical import. As an instance of his simple method of dealing with puzzling points we may quote his lucid little discussion on the origin of the presystolic murmur in cases of pure aortic regurgitation, the murmur that is associated with the name of Austin Flint. His classification of mitral stenosis, again, is of real practical the Poor-law. The cause of the delay in placing this unfortunate man where he could best be taken care of seems to have been due to the attitude of the police, which must surely be unusual. It is their duty to remain in charge of a person who is in their custody in consequence of the crime he has committed in attempting to take his own life and it is equally their duty to afford him the best chance possible of having his life saved. A visit to a few of the London hospitals would soon convince the police of Chelmsford that there is "power to put the police in charge," and that it is very frequently done in the metropolis, where the Home Office would quickly interfere if such a course were a wrong one to adopt and detrimental to the public service. Even with a constable remaining present to render assistance if needed the desirability of admitting an insane patient must be one for the consideration of the hospital committee, to be determined according to the patient's condition. Without such assistance it would be wrong for the hospital to undertake a responsibility to a large extent outside its province.

Parental Liability.

The *Journal of the American Medical Association* records an interesting case in regard to the liability for fees incurred by a parent who had requisitioned the extraordinary services of a medical man on behalf of his adult son. The plaintiff sued for \$16,000 as a reasonable remuneration for having been in constant and exclusive attendance on the defendant's son for 40 days before his death. He had been summoned for this purpose by an urgent telegram from the father, which the plaintiff contended constituted an implied contract of liability for reasonable fees. The defence was that from \$4000 to \$6000 was an ample fee for the services rendered. The plaintiff secured a verdict for \$12,666. The defendant, however, moved for a new trial on the ground of error in the instructions and that the verdict was excessive, and this was sustained by the trial court. The Supreme Court has affirmed this order. The decision was embodied in a lengthy judgment which affirmed, *inter alia*, that the jury had been wrongly instructed when told to take into consideration the defendant's wealth and the plaintiff's general professional reputation when assessing the award.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 11th, 1829.

REMUNERATION TO MEDICAL WITNESSES.

To the Editor of THE LANCET.

SIR,—Can you or any of your numerous readers inform me, whether a regularly educated medical man, a member of the College, &c., who is called to the case of a drowned person, uses every means to restore to life the said drowned person, and afterwards is obliged to attend the inquest upon the body; whether this medical man is not entitled by law to some remuneration? In asking the question, I speak feelingly, having been called to several cases of this kind, and, indeed, I was called up in the middle of the night to one, only the early part of this week.

I remain, Sir,
Your obedient servant,
HORATIO COLLMAN.

6, London Terrace, Hackney Road,
June 27th, 1829.

Such is the disgraceful state of the law regarding the medical profession, that a medical man, thus circumstanced, cannot legally recover compensation for his time and trouble!—ED. L.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8255 births and 3853 deaths were registered during the week ending July 6th. The annual rate of mortality, which in the successive weeks of last quarter had declined uninterruptedly from 17·9 to 12·5 per 1000, was again 12·5 in the week under notice. During the 13 weeks ending June 29th the death-rate in these towns averaged 15·1, the rate in London during the same period being 14·6. The lowest rates last week in the 76 towns were 4·1 in Walthamstow, 5·2 in Hornsey, 6·0 in Northampton, and 6·2 in King's Norton; the highest rates were 18·4 in Sunderland, 18·5 in Bolton, 18·6 in Bury, 18·9 in Blackburn, 19·6 in Burnley, and 20·0 in Middlesbrough. The 3853 deaths in the 76 towns were seven in excess of the number in the preceding week and included 366 which were referred to the principal epidemic diseases, against 430, 365, and 427 in the three preceding weeks; of these, 130 resulted from measles, 109 from whooping-cough, 47 from diarrhœa, 41 from diphtheria, 32 from scarlet fever, and seven from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered in Willesden, Southampton, Plymouth, Northampton, Devonport, or in ten other of the 76 towns; the annual rates from these diseases, however, ranged upwards to 3·1 in Blackburn, 3·3 in Derby, 3·7 in Bolton, 5·3 in Wigan, and 5·4 in Walsall. The 130 fatal cases of measles showed a decline of 28 from the number in the previous week, the highest annual rates therefrom being 1·8 in Hull, 2·3 in Bolton, 2·5 in Derby, 3·5 in Wigan, and 4·9 in Walsall. The 109 deaths from whooping-cough were 27 fewer than the number in the preceding week, the death-rates from this disease ranging upwards to 1·0 in Leeds, 1·1 in Bolton, 1·4 in Merthyr Tydfil, 1·8 in Wigan and in Bury, and 1·9 in Tynemouth. The fatal cases of diarrhœa, which had been 50, 53, and 51 in the three preceding weeks, declined to 47 in the week under notice. The 41 deaths from diphtheria exceeded by 11 the number in the preceding week, the greatest proportional mortality from this disease being recorded in Huddersfield. The deaths from scarlet fever, which had been 32 and 40 in the two preceding weeks, declined again last week to 32. The seven fatal cases of "fever" included two in Liverpool and two in Burnley. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2936, 2985, and 3022 at the end of the three preceding weeks, had further risen to 3193 at the end of last week; 504 new cases were admitted during the week, against 389, 414, and 422 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 156 in each of the two preceding weeks, declined last week to 148, but were 18 in excess of the corrected average number in the corresponding week of the previous five years. The causes of 31, or 0·8 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, and in 56 other of the 76 towns; the proportion of uncertified deaths, however, showed a marked excess in Liverpool, Birmingham, Sheffield, Gateshead, and St. Helens.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 17·3 and 15·0 per 1000 in the two preceding weeks, further declined to 14·5 in the week ending July 6th, but was 2·0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·2 in Greenock and 11·7 in Aberdeen to 15·3 in Glasgow and 19·3 in Leith. The 504 deaths in the eight towns showed a decline of 18 from the number in the preceding week, and included 59 which were referred to the principal epidemic diseases, against 84 and 76 in the two preceding weeks. These 59 deaths were equal to an annual rate of 1·7 per 1000, which exceeded by 0·5 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 18 which were referred to whooping-cough, 18 to "fever," 10 to diarrhœa, six to diphtheria, five to measles, and two to scarlet fever, but not any to small-pox. The deaths from whooping-cough, which had declined from 57 to 34 in the four preceding weeks, further fell last week to 18, of which ten occurred in Glasgow, three in Edinburgh, three in Dundee, and two in Aberdeen. The fatal cases of "fever," which had been 14 and 21 in the two previous weeks, declined again to 18 last week, and included ten of cerebro-spinal meningitis in Glasgow, three in Edinburgh, and three in Leith. The deaths from diarrhœa, which had been 23 and 13 in the two preceding weeks, further fell last week to ten, of which six were registered in Glasgow and two in

Correspondence.

"Audi alteram partem."

THE MEDICAL SICKNESS AND ACCIDENT SOCIETY.

To the Editors of THE LANCET.

SIRS,—In 1884 it occurred to some medical men that the too frequent sending round of the hat on behalf of members of the profession who were incapacitated by illness or accident could best be obviated by the founding of a society formed for, and managed by, medical men only.

Accordingly the Medical Sickness and Accident Society was started. Membership was confined to registered medical men and licentiates of dental surgery practising in the United Kingdom. For an annual contribution, varying with the age of entry from about £6 at the age of 21 years to about double that amount at the age of 50 years, members secure a weekly allowance of £4 4s. while they are prevented by any kind of illness or accident from performing professional work. The full amount may be drawn for 26 weeks and after that half pay is allowed for any period of disablement right up to the age of 65 years. From the commencement the society has been a great success. Over 400 members joined at once in 1884 and the membership has grown until last year it amounted to 2488. The society was registered under the Friendly Societies Act and thus has no shareholders, so that all the funds belong to the members. The committee of management, selected by the members, give their services gratis, and in every way the society is worked with great economy. It has paid to its members over £100,000 in sickness claims and has now a reserve fund of over £200,000.

It would be difficult to estimate the amount of benefit which the members have derived from its operations. Year by year the amount of sickness pay disbursed has grown from a few hundreds in 1884 to £11,494 in 1906. Letters received at the office show how much this sick pay is appreciated by the members. In all cases it lessens the inconvenience caused them by the loss of professional earning; in not a few it has saved them from serious embarrassment; and in some it has stood between them and actual privation. More particularly is it found valuable in those cases where there is little or no hope that the member will ever again be able to do professional work. In such cases the society provides a practically permanent provision generally amounting to £109 4s. a year, and over a score of members are now drawing these annuities. Less than 5 per cent. of the premium income has been spent in management and the savings thus effected enable the committee to pay a handsome cash bonus to members reaching the age of 65 years. In all more than £12,000 has been returned to the members in cash bonuses.

The society has no agents and pays no commission for new business. It has grown steadily through the natural canvassing of the many members who have enjoyed its benefits. The registered office is at 33, Chancery-lane, London, W.C.

I am, Sirs, yours faithfully,

Walthamstow, July 2nd, 1907. ST. CLAIR B. SHADWELL.

THE SANDGATE "SANATORIUM."

To the Editors of THE LANCET.

SIRS,—You will understand that as one of the persons mainly responsible for the Sandgate Sanitary Powers Act I have been greatly interested in your recent articles upon this subject.

I should like in this place to repeat the advice which I gave to the Sandgate council—viz., that their proper course was to refuse to license the hospitals. I am convinced that if this course had been followed the present nuisance would by this time have ceased to exist and that the fear of compensation which dominated the minds of the council would have been found to be as groundless as most fears which are met boldly and conscientiously. Unfortunately, in the face of ignorant and captious criticism within and without the council, the latter lacked the courage of what I believe to have been their convictions.

My main object in writing to you is, however, to comment upon the last paragraph of the article in THE LANCET of June 29th. An ironical excuse is there made for the masterly inactivity of the Local Government Board, and my fear is lest the matter-of-fact mind should fail to perceive the irony. In Sandgate a special law prevails, made specially for Sandgate in circumstances confined to Sandgate. The object of the particular legislation was to get rid of a nuisance; the machinery to be employed was a code of regulations. Private interests were safeguarded by a compensation clause in the special Act. If, therefore, the regulations proposed by the council would result in closing the homes, where would be the objection in principle? What general precedent would this establish? Surely none except that a law made avowedly for a specific purpose should be honestly enforced. The excuse put into the mouth of the Local Government Board that "regulations which would have led to the closing of all homes at Sandgate, if applied generally, would cause the abolition of half the hospitals for tuberculosis in the country" rests for its speciousness upon the words *if applied generally* and therefore ex-hypothesi the excuse fails.

The fact is that the Local Government Board has made up such mind as it possesses that the Act shall remain a dead letter until such time as the Board shall see fit to bring forth a general measure of its own. I ask, is this honest? People complain of so-called judge-made law: with how much more reason might they complain of departmentally stifled laws?

What has Sandgate, what has the nation at large to expect between departmental dishonesty and departmental ineptitude? The fault lies, as your Special Commissioner long ago pointed out, in the political and partisan constitution of the Local Government Board.

I am, Sirs, yours faithfully,

Sandgate, July 2nd, 1907. L. J. D. BROCKMAN.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—I have pleasure in answering the queries which Dr. J. Cunningham Bowie has put to me at the conclusion of his letter to you which appears in THE LANCET of June 29th.

1. The current for the primary is from the main and its voltage is 250. The amperage to the primary varies, not only according to the amount of output desired but also according to the form of interrupter used. When a fairly full dose is to be given I use my Gaiffe jet interrupter with a current of from two and a half to three ampères. When a specially small or specially large dose is required I use the friction break, with a minimum of two or a maximum of six ampères.

2. The maximum voltage of my high-frequency apparatus I calculate at about 80,000, whilst the maximum current obtainable is from 700 to 800 milliampères. I seldom apply more than 500 milliampères.

3. When measuring the potential difference between any two points of the body, as hand and forearm or neck and groin, a metallic electrode is applied to each point, and these are connected by a wire to either side of the spinthermeter, and the greatest distance across which a spark can leap is taken as the potential difference in millimetres between these parts of the body of the patient. In measuring the current to zero from any region of the body a metallic electrode is applied to that region and connected by a wire to the water main of the house, the high frequency milliampère meter being in series—that is, between the electrode and the water pipes.

4, 5, and 6. It may simplify matters and prevent repetition if I reply to these questions together. In the case of the potential difference measurement the external circuit is, of course, in parallel with the circuit between the points being measured. In the case of the measurement of the current to zero the external circuit is shunted off to earth from the point which is having its milliampèrage measured and therefore this circuit may be said to be in parallel with the parts of the body of the patient beyond this point. It is possible that a diagram may be necessary to explain this fully, but I hardly think so.

Dr. Bowie must have observed that I have dealt in my paper with the effects of high-frequency currents not according to either the quantity or the quality—voltage, &c.—of

Besides all this there is the very generous promise of support from the King's Fund, in the event of amalgamation, by (1) contributing for five years the annual sum of £1500; and (2) guaranteeing the rent of the premises of the North-West London Hospital in the Kentish Town-road for ten years, and paying the cost of adapting these premises as an out-patients' department to the amount of £2000.

The question as to whether or not the Hampstead practitioners would suffer by the transaction is not one which should influence the public in their decision. The point at issue is, Will these charitable institutions, to which the public have so generously subscribed, be thereby benefited? To the unprejudiced mind there can be but one answer: both institutions will undoubtedly in the truest sense be strengthened and their sphere of usefulness extended. It should be remembered that in carrying out a scheme such as this there must of necessity be changes involving cases of individual hardship; this is especially the case here at the North-West London Hospital. But it is gratifying to know that every one whose personal interest is at stake, be he doctor or layman, is prepared to stand on one side rather than put the smallest hindrance in the way of an undertaking which we all believe to be on the whole a wise and beneficent one. I am, Sirs, yours faithfully,

ALFRED CRASKE, Secretary.

North West London Hospital, Kentish Town-road, N.W.,
July 8th, 1907.

PHYSICAL EXAMINATION OF SCHOOL CHILDREN.

To the Editors of THE LANCET.

SIRS,—In your report of the proceedings of the Standing Committee on Mr. J. Wilson's Public Health Bill in THE LANCET of July 6th, p. 67, I am reported, probably owing to necessary condensation, as opposing the examination of children in elementary schools for infectious disease by the medical officer of health.

Clause 82 was so drawn that power would be given to the medical officer of health to make an extended physical examination of every child as well as to examine it for infectious disease. This was objected to, and Sir William Collins put down an amendment requiring that before any physical examination was made the written consent of the parent or guardian should be obtained. In supporting this amendment I pointed out that such written consent had usually to be obtained in secondary schools and I was opposed to the children of the poor being *made* to submit to a physical examination while the child of the richer parent would escape.

I am, Sirs, yours faithfully,

July 6th, 1907. GEORGE COOPER.

AN ASPECT OF VACCINES AND ANTITOXINS.

To the Editors of THE LANCET.

SIRS,—The halo of individuality which modern science sheds round the agents submitted for special uses tends to limit observation within the lines suggested. It is open to doubt whether this is entirely good. Specially is it questionable in such remedies as are derived from the blood of man or animals. The vaccines, serums, and antitoxins may contain recognisable individual products which have specific uses, but their life-history and the mode of their production class them with possible family associations which may be serviceable under other and not always allied conditions. It is now everywhere admitted that the lymph which Jenner used in his vaccinations was not even bacteriologically pure; the admission is ample reason for all the research which has placed his operation on the sound basis which is the foothold of its present advocates. One, perhaps two, observations must have fallen to the lot of most medical men; the first, that vaccination performed in the early stages of some previously existent disease was frequently delayed, or prevented, in its evolution; secondly, that infantile eczema or impetigo was not a bar to successful vaccination, but rather that the successful vaccination was sometimes followed by a disappearance of the eczema. My own experience would tend to show that this result followed more frequently after the use of humanised lymph than with the more pure and individualised calf products. The eldership of vaccinia should have placed it in the forefront of individuality as regards its scientific purity. My object in this note is to call attention to some possible bye-products, or nuclein derivatives, which may exist in the next elder of the serums.

Some years since I was called upon to give a protective dose of the antidiphtheritic serum to several members of a family, one of whom was the subject of persistently recurring boils. To my great satisfaction the boils ceased immediately after the injection. The observation was too trite to be neglected. I offered to repeat the experiment in other cases of the same nature, as well as in cases of carbuncle. The results have convinced me that it is of great value and is usually successful. In some of my cases there was evidence of sugar in the urine, but I have not had the opportunity to use the serum in the carbuncles of confirmed diabetes. I tried it without success in the pustular rash which sometimes attends the continuous administration of bromides. We see so little septic disease in Guernsey that one's stock of antistreptococcic serum is apt to grow stale. Once I required some under these conditions and was shut off by a Sunday's post from obtaining more till the Tuesday. As a "do-no-better" I used the antidiphtheritic serum and with such good result that no other was required.

My first, and accidental, result was obtained from the use of 500 units, but in the selected cases I have used 2000 units. I have no hesitation in asking for an extended trial of it in cases of boils and carbuncles; all my patients have been most grateful. Once again, the use of antistreptococcic serum is somewhat disturbing in early childhood. An infant was born of a mother who died 14 days later from puerperal septicæmia in India. The child had an abscess opened near the anus before it fell under my care, and it had a purulent discharge from the ear as well as a maintained temperature, which if it seldom reached above 100° F. also failed to touch the normal lower temperature of the day. After consultation with the uncle (who is an M.D., T.C.D.) I injected 500 units of the antidiphtheritic serum and the result was satisfactory. The ear discharge ceased, the temperature became normal, and the division of a small sinus near the anus restored the infant to perfect health. There is no finality in these results; they only raise the question of a limited individuality of the serums and perhaps suggest the lines of search for their family relationships.

I am, Sirs, yours faithfully,

Guernsey, June 21st, 1907. J. AIKMAN, M.D. Glasg

MSS. OF JOHN HUNTER'S LECTURES.

To the Editors of THE LANCET.

SIRS,—I possess a volume described on the back as "Hunters Surgery MS." which appears to be different from any which you have mentioned. It is written throughout in the first person (and beautifully written), contains 67 lectures, 422 quarto pages, with five more pages of index. The only indication of its date might be found in the following passage in the beginning of the first lecture: "This course will consist of about eighty lectures in wch (*sic*) I shall differ very much from what is taught in books upon this subject. I do not undertake to advance anything but what is built upon my own observations made in an attentive practice of 40 years and upwards." The index is a most careful *précis* of each lecture—for example, lect. 13—

> Acquir'd Hereditary causes (of disease), Effects *of* y^e mind on disease, Involuntary actn of voluntary parts, Symptoms, Anomalous symptoms, the difference in y^e power of resist'g disease in y^e different Structure of parts.

I would not like to part with the volume, which I regard as a precious heirloom, but if it is original the R.C.S. must have it. I am, Sirs, yours faithfully,

Southport, July 6th, 1907. COLIN CAMPBELL.

THE APOTHECARIES ACT, 1907.

To the Editors of THE LANCET.

SIRS,—In view of the numerous inquiries I am receiving from those holding the diploma of the Society of Apothecaries as to the effect of the Act upon their diploma, may I be allowed to state that the result of the Act, so far as concerns those who have obtained the "L.S.A." since June 30th, 1887, is to enable them *on application to the Society* and on payment of the prescribed fee to have granted to them a diploma conferring the qualification of "Licentiate in Medicine and Surgery of the Society of Apothecaries." Subject to give fair trial to new methods of treatment. He was a good friend with a generous nature, always encouraging to his juniors and active in assisting them. Hundreds of his old pupils and resident officers owe their success to his teaching and example and bear for him an affection which he reciprocated. Others than the writer may remember among his other hospitalities the delightful evening which he afforded to them, and not less to himself, in entertaining at dinner those who had been his house physicians during his 25 years' service at St. Mary's. He was ever a loyal and esteemed colleague, no better testimony of which could be found than the fact that when the period came for his retirement the staff unanimously petitioned the governing board to alter the laws of the hospital that he might benefit the hospital by an additional five years as visiting physician."

The details of Sir William Broadbent's last illness are probably known to most of our readers, for he never desired that any mystery should be made about them. Some nine months ago he had a severe attack of pneumonia. An empyema followed which was successfully relieved by operation, but he did not recover his strength. Latterly, however, he appeared to be making real progress, but at the end of last week symptoms of fever recurred, on Tuesday evening his condition became very grave, and he died on Wednesday morning, July 10th.

Sir William Broadbent married, in 1863, Eliza, daughter of Mr. John Harpin, of Birks House, Holmfirth, Yorkshire, by whom he had two sons and three daughters. His two sons, Dr. John Francis Harpin Broadbent, who succeeds his father in the baronetcy, and Dr. Walter Broadbent, are both members of the medical profession.

It has been arranged that the funeral shall take place on Saturday. The first part of the service will be held at St. Peter's, Vere-street, Oxford-street, at 11 30 A.M., and Canon Page Roberts will officiate. Afterwards the remains will be removed from London for interment at Wendover, Bucks.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the second professional examination in Anatomy and Physiology on June 27th and 28th and July 1st and 2nd 95 candidates presented themselves, of whom 56 were approved and 39 were rejected. The following is a list of successful candidates:—

Rupert Blake Adams, St. Mary's Hospital; Francis Cooke Alton, St. Thomas's Hospital; Dinsha Darasha Barla, L.M. & S. Bombay, Bombay University; Albert Malcolm Barlow, London Hospital; Frank Bashford, St. Mary's Hospital; Maurice Beddow Bayly, Charing Cross Hospital; Edward Charles Beddows, Birmingham University; Guy Capper Birt, St. Thomas's Hospital; William Percy Bonner, London Hospital; Edward Moxon Browne, St. Bartholomew's Hospital; Edward Spencer Calthorpe, Charing Cross Hospital; Ralph George Dainty, Charing Cross Hospital; Samuel Danziger, Victoria University, Manchester; Frederic Nicklin Doubleday, Guy's Hospital; Arthur Downes, St. Bartholomew's Hospital; Frederick Charles Endean, M.P.S., Guy's Hospital; Hugh Arthur Evans, Westminster Hospital; Gilbert James French, Victoria University, Manchester; Gilbert Henry Colling St. George Griffiths, University College, Bristol; Alfred Edward Hamlin, St. Bartholomew's Hospital; Leonard Austin Harwood, Westminster and King's College Hospitals; Charles Ernest Howden, New Zealand University and London Hospital; Herbert Richard Barnes Hull, University College, Bristol; Stanley Gower Johnson, Middlesex Hospital; Homi Dorabji Kanga, B.A., L.M. and S. Bombay, Bombay University; Charles Haley Knowles, Leeds University; John Murgatroyd Land, Leeds University; Manly McWhinnie Lopez, University College, Bristol; Donald McCully, University College; Raymond Gabriel Maglione, Victoria University, Manchester; Philip Stanley Martin, University College; Henry Sinclair Mason, St. Mary's Hospital; Guy Matthews, King's College Hospital; James William Edwin Mendis, L.M. and S. Ceylon, Ceylon Medical College and King's College; Cyril Cassan Messiter, B.A. Cantab, Cambridge University and St. Bartholomew's Hospital; Thomas Alexander Milroy, Otago University and Glasgow University; Robert Sydney Overton, St. Thomas's Hospital; Percy Edward Hughes Patey, Guy's Hospital; Harry Platts, Guy's Hospital; Richard Bancroft Nevil Reade, St. Mary's Hospital; William Alfred Reynolds, University College, Bristol; Ernest Arthur Runting, Middlesex Hospital; Alec Linford Saul, Guy's Hospital; Edward Argent Saunders, Middlesex Hospital; William Shipton, B.A. Cantab., St. Thomas's Hospital; William Faulkner Valentine Simpson, London Hospital; Reginald Samuel Sherard Statham, University College, Bristol; Martin Phillips Thomas, B.A. Wales, King's College Hospital; Graham Yalden Thomson, Guy's Hospital; Walter Vincent Tothill, London Hospital; Ronald Herbert Vicary, Cambridge University and St. Mary's Hospital; Percy Boyd Wallis, Cambridge University and King's College Hospital; Alexander Watson, London Hospital; John Ernest Price Watts, Westminster and King's College Hospitals; Gerald Whittington, Charing Cross Hospital; and Frederick Cecil Wright, St. Bartholomew's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Chemistry.—H. Cox, Birmingham; V. P. Norman, Durham; and C. B. Welsby, London Hospital.

Materia Medica and Pharmacy—W. C. D'Eath, Charing Cross Hospital; and F. S. Hawks, King's College Hospital.

PART II.

Anatomy.—T. C. Clarke and W. E. Dimond, Liverpool; W. H. S. Hodge, St. Bartholomew's Hospital; W. S. Hughes, Charing Cross Hospital; E. M. Johnstone, Royal Free Hospital; J. A. Jones, Manchester; L. F. G. Lewis, St. Bartholomew's Hospital; D. J. McKinnon, Aberdeen; and P. E. H. Patey and H. C. Pugh, Guy's Hospital.

Physiology.—T. C. Clarke, Liverpool; E. C. Fisher, Royal Free Hospital; W. H. S Hodge, St. Bartholomew's Hospital; E. M. Johnstone and A. Jonathan, Royal Free Hospital; J. A. Jones, Manchester; L. F. G. Lewis, St. Bartholomew's Hospital; and H. I. Welsh, St. Mary's Hospital.

UNIVERSITY OF BIRMINGHAM: FACULTY OF MEDICINE.—The following is a list of the successful candidates at examinations held in June:—

I. *Degree of Doctor of Medicine.*—Leonard George Joseph Mackey.

II. *Degrees of Bachelor of Medicine and Bachelor of Surgery.*—(*a*) Past student of Birmingham Medical School: William Frederick Ewart Ashton. (*b*) Under Ordinary Regulations: Class II.: Herbert Charles Horace Bracey, *†James Fenton, Philip James Mason, Nevill Coghill Penrose, Arthur Addison Sanders, Arthur John Smith, Rupert Wesley Thompson, and Herbert Henry Warren.

III. *Fourth Examination for the degrees of M.B., Ch.B.*—Class I.: *John Dale. Class II.: John Adams, Charlotte Bailey, George Henry Chavasse Mold, David Priestley Smith, Harold Cairns Terry, and Edward Vernon Whitby.

IV. *Third Examination for the degrees of M.B., Ch.B.*—*Part I., Pathology and Bacteriology.*—Class I.: *Herbert Henry Sampson. Class II.: Walter Charles Blackham, Norman Alexander Boswell, Harold Gordon Browning, Mary Clarke, John Selwyn Edwards, Harvey Atkins Evans, Humphrey Francis Humphreys, George Frederick Jotham, Violet Maud McCready, John Lichtenstein Ritchie, Harold Cairns Terry, Ethel Annie Waldron, and Kenneth Douglas Wilkinson. *Part II., Materia Medica and Pharmacy*—Class I.: *Herbert Henry Sampson. Class II.: Walter Charles Blackham Norman Alexander Boswell, Harold Gordon Browning, Mary Clarke, Humphrey Francis Humphreys, George Henry Chavasse Mold, Carl Euclid Molino, John Lichtenstein Ritchie, Ethel Annie Waldron, Harold Arthur Whitcombe, and Kenneth Douglas Wilkinson.

V. *Second Examination for the degre s of M.B., Ch B*—Class II.: Eric Walter Assinder, *Oscar Madeley Holden, Elizabeth Stephens Impey, and Ronald Douglas Nelson. Completed Examination: Charles William Hayward and Arthur Harry Newton. Passed in part of the Examination: Arthur McLean Pickup (Physiology and Comparative Anatomy) and (Henry Richmond (Biology).

VI. *First Examination for the degrees of M.B., Ch.B.*—Class I.: George Ernest Elkington. Class II.: Evan Davies, Christopher Charles Cole Court, John Lewis Anderton Grout, Travis Hampson, Charles Crawford Jones, Arthur Christopher Tibbits, Albert Joseph Tonkinson (External), and Alan Ayscough Wilkinson. Completed Examination: Charles Ernest Salt. Passed in part of the Examination: George Herbert Alabaster (External) (Chemistry and Physics, Robert Baxendell Coleman (Physics and Biology), Vivian Francis Eling Fox (Chemistry and Biology), and Percy Alfred Newton (Chemistry and Biology).

VII. *Second Examination for the Diploma in Dental Surgery*—Alan Ayscough Wilkinson.

VIII. *Diploma in Public Health.*—*Parts I. and II.*: Ernest Frederick Wharton Bywater. *Part I.*: Tom William Beazeley and Alfred Ernest Remmett Weaver.

* Queen's scholarship. † Ingleby scholarship.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following candidates were successful:—

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Adrian Stokes, Charles M. Finny, Marius A. Diemont, Hilgard Müller, Roelif A. Albertyn, Vicars M. Fisher, Beatrice M. Hamilton, Perceval G. Leeman, Victor G. Best, David Duff (Sch.), John H Woodroffe, Edmund F. Lawson (Sch.), John G. Ronaldson, Arthur C. Hallowes, Benjamin A. Molyneux, Louis Trichard, John G. Dods, Edward P. Allman-Smith, Edwin B. Bate, Brinsley H. Moore, and Charles Pentland.

Part II.—Albert J. Stals, John D. Kernan, Cecil P. Smyly, David Duff (Sch.), Benjamin A. Molyneux, Edwin B. Bate, Alexander E. Cosgrave, Louis Trichard, Hugh S. Metcalfe, and William A. Nicholson.

FINAL MEDICAL EXAMINATION.

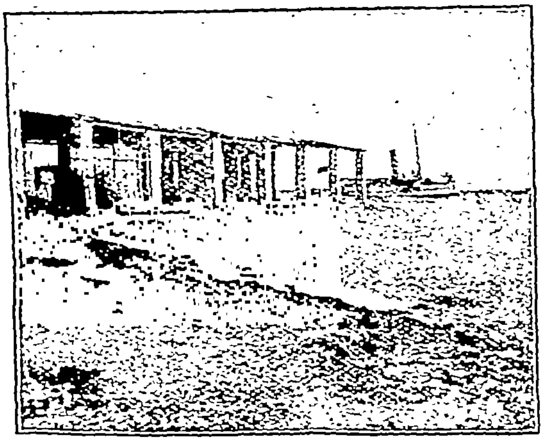
Part I.—Johannes C. Pretorius, John A. W. Ponton, Richard P. Hadden, Henry H. Ormsby, Charles W. Laird, Albert H. Wynne, William E. Hopkins, Samuel F. Charles, Frank Smartt, David G. Madill, Albert V. J. Richardson, James F. Clarke, George Halpin, Herbert V. Stanley, Gerald G. Mecredy, Dixie P. Clement, Arthur H. Laird, George B. M'Hutchison, Ernest C. Lambkin, Alexander S. M. Winder, James P. S. Dunn, Norman P. Jewell, and William H. M'Carthy.

PREVIOUS DENTAL EXAMINATION.

Anatomy and Institutes of Medicine.—George Elliott.

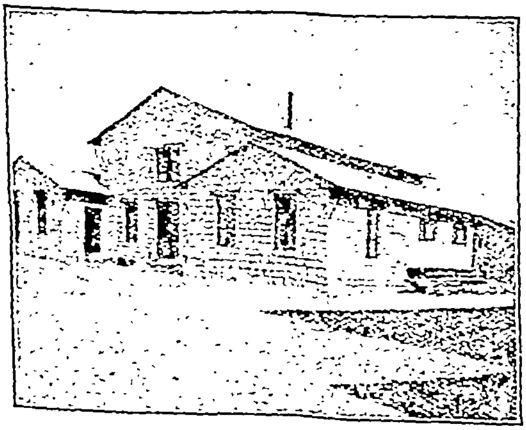
to a point where the water is deep enough to allow boats to come alongside. The Abu-Saad pier as it was before the repairs were begun is seen in Fig. 34. It is covered with a roof, supported on stone pillars, and this also has been thoroughly repaired. The absence of a landing-pier at Abu-Ali has hitherto rendered that island useless; the Commission's recommendation to construct there a pier 35 metres long and three wide is now being carried out. The amount of superficial space being extremely limited, even taking all the three islands together, it is a matter for regret that many of the existing buildings have been put up with very little thought of symmetry or of any general plan of the institution as a whole. In this way some valuable space has been lost. It is too late to remedy this defect now and all that can be done will be to employ the land still remaining free to the greatest advantage and to establish the best general plan of the lazaret that can be attained without removing existing buildings. The island of Abu-Saad is now very largely built over; on that of Wasta there is a considerable amount of space left, but the presence of two old and six new houses for pilgrims—the former irregularly placed and the latter occupying a line running down the middle of the island—compels the adoption of a plan for this island which lacks symmetry (as shown in the accompanying sketch) but which is the best possible in the circumstances. On Abu-Ali no buildings have as yet been put up and here it is proposed to build the hospital for cholera or plague, to be mentioned later.

FIG. 34.



Landing pier at Abu-Saad and steam tug *Zulal*.

FIG. 35.



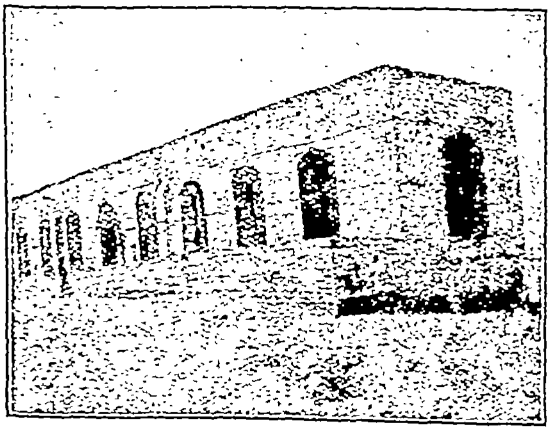
Disinfecting pavilion, Abu-Saad.

There is at present only one disinfecting pavilion for this lazaret. It is seen in Fig. 35. It is a masonry building recently constructed; the ground plan of it is excellent. It is much smaller than the corresponding buildings at Camaran described in an earlier article. On the male side there are 16 douche baths and on the female side six. There are two steam disinfecting stoves. A number of improvements in detail of this pavilion are recommended in the Commission's report, but they scarcely need be mentioned here; most of them have been already, or are being, executed. In the plan of Wasta prepared by the Commission a space is left near the landing jetty for the future construction of a second disinfecting pavilion. This will do away with the necessity of landing pilgrims destined for Wasta at Abu-Saad to undergo their disinfection, after which they have again to be put on their sambouks and towed from that island to Wasta.

Perhaps the most serious defect of this lazaret in its existing state is the lack of separation between different groups of pilgrims interned there at the same time. Hitherto the most that has been done in this respect has been to fix some posts in the ground and run a cord between them. It is obvious that this constitutes no real separation of any kind. The Commission's recommendation to divide the islands up into "cordons" or camps and to surround these by high wire fences will very shortly be carried out. The fences will be of the same character as those recommended for Camaran and described in an earlier article. The lines which these fences will follow and the shape and size of the cordons thus established are seen in the accompanying sketch plans of Abu-Saad and Wasta. (Plan V.)

The pilgrims are lodged either in stone houses or in tents, the "arish," or mat-and-thatch house in use at Camaran being almost unknown in the Jeddah neighbourhood. There are four large stone houses on the Abu-Saad island, each capable of holding 80 pilgrims; on Wasta there are two old houses of the same kind and size as those at Abu-Saad, and six new smaller houses. The latter were in course of construction when the Commission visited the lazaret; they have since been completed, as also three quite small single-roomed houses on Wasta and two on Abu-Saad. These latter were intended to serve as kitchens, but as the Commission pointed out, land is too scarce and valuable to permit of using so much of it for kitchens, more particularly as most of the pilgrims carry portable cooking stoves with them or are adept at improvising kitchens on the sand. The five small houses in question have consequently been modified in the course of construction and been converted, some into houses "of distinction," one into a lodging for the sanitary guards, and one into the office of the lazaret.

FIG. 36.



House for pilgrims in quarantine, Wasta.

The old houses for pilgrims are 31 metres in length and 6·10 metres in width. They are built of the madreporic stone which is found in abundance in the neighbourhood of Jeddah. The roof is of "tap-tap," the nature of which was described in Article III. They all require thorough repair, and it has been decided not only to strengthen and to repair the walls but also to add a parapet round the flat roofs, with an outer stair at one end of the building to give access to the roof; to replace the rough stone flooring of the interiors by a flooring of cement; to add a covered verandah along one side at least of each of the houses; and to carry out certain other enlarged by the addition of two new wards. The Sleeping Sickness Hospital has been practically rebuilt, the walls having been considerably heightened and a cement floor and tin roof added. The present site of the Sleeping Sickness Laboratory has been thought unsuitable for many reasons. A new laboratory with large out-buildings and houses for the staff are under construction at a spot on the peninsula outside the township boundary. New hospitals and dispensaries have been built at Kampala, Jinja, Hoima, and Mbarara. There are no Government Asylums, poor houses, reformatories, &c., in the Protectorate.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following prizes were awarded for the summer session. Barker anatomical prize (£31 10*s.*): G. S. Levis. Carmichael scholarship (£15): J. Menton. Gold medals in operative surgery: P. G. M. Elvery and T. Sheehy (equal). Stoney memorial gold medal in anatomy: Miss I. M. Clarke and G. C. Sneyd (equal). Practical histology: F. W. Warren, first prize (£2) and medal; and J. S. Pegum, second prize (£1) and certificate. Practical chemistry: H. C. Gilmore and J. Kirker (equal), first prize (£2) and medal. Public health and forensic medicine: H. Hunt, first prize (£2) and medal; and Miss C. F. Williamson, second prize (£1) and certificate. Materia medica: J. Menton, first prize (£2) and medal; and Miss C. F. Williamson, second prize (£1) and certificate. Biology: J. T Duncan, first prize (£2) and medal; and P. V. F. Crowe, second prize (£1) and certificate. The lectures and practical courses of the winter session will commence on Tuesday, Oct. 15th.

PLAS MARIANDIR.—Some weeks ago it was mentioned by our Manchester correspondent that Plas Mariandir, at Penmaenmawr, had been taken as a seaside home for convalescents by the recently formed "Manchester and Salford Hospital Saturday and Convalescent Homes Fund Incorporated." (Surely the time is ripe for some genius to devise a simpler nomenclature for many of our institutions.) The formal opening by the Lord Mayor of Manchester took place on June 29th. The funds for the acquirement of the institutions—that at Arnside for women and that at Penmaenmawr for men—were raised by a bazaar in Manchester in the autumn of 1905. It is hoped, however, that they will be maintained and the convalescent homes movement be developed by the Hospital Saturday Fund, and also that the contributions on behalf of the hospitals will be increased. This seems a sanguine anticipation, but there is no doubt as to the ability of those interested to do this if they set themselves to the task. The present accommodation is for 45 or 50 men, and there is room for some enlargement. The urban council gave a luncheon to the Manchester and other visitors.

LITERARY INTELLIGENCE.—The next addition to the Oxford Medical Publications, to be ready next week, is "Operations of General Practice" by Mr. Edred M. Corner and Dr. H. I. Pinches. The volume contains upwards of 175 illustrations and it is meant to be a guide to the general practitioner in the performance of the more strictly surgical part of his daily routine. The Oxford University Press announces also that the first of the seven volumes of Professor Osler's "System of Medicine" is almost ready for publication. This volume deals with predisposition and immunity; diseases caused by physical, chemical, and organic agents, by vegetable parasites, by protozoa, by animal parasites, nutrition, and constitutional diseases. It has been arranged that the volumes shall be obtainable separately.—In our notice of the *Medical Directory* published by the American Medical Association which appeared last week we omitted to state that the Directory can be purchased from Messrs W. B Saunders Company, 9, Henrietta-street, Covent Garden, W.C It is not necessary to apply to the American Medical Association for copies, as might have been gathered from our review.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Society of Apothecaries of London Act.

AMONGST the Bills which received the Royal Assent last week was the Society of Apothecaries of London Bill.

The Home Work Inquiry

Amongst the witnesses who have given evidence before the select committee of the House of Commons which is inquiring into home work is Dr. R Dudfield, medical officer of health of Paddington. He strongly urged on the committee that persons who took work to their own homes and performed it there for wages should register themselves with the local authorities Without an arrangement of this kind complete protection from the spread of infectious diseases was impossible, especially in view of the fact that there was no compulsory notification of measles, whooping-cough, or phthisis.

A Royal Commission on Whisky

The Government proposes to recommend the appointment of a Royal Commission to inquire into, and report upon, the various questions raised by recent litigation as to what constitutes "whisky" The President of the Local Government Board, however, states that he cannot yet give the terms of reference to the Commission, nor have the names of the Commissioners been announced It is expected that the Commissioners will include amongst them several chemical experts and representative gentlemen in the whisky trade, as well as one or two lawyers

King Edward's Hospital Fund for London.

The King Edward's Hospital Fund for London Bill has been read a third time in the House of Commons

Lunacy in Scotland.

The forty-ninth annual report of the General Board of Commissioners in Lunacy for Scotland has been presented to Parliament. In their report the Commissioners express their deep regret at the death of Sir JOHN CHEYNE, K.C, who had been a member of the Board since 1895 They go on to state that on Jan. 1st of the present year, exclusive of insane persons maintained at home by their natural guardians, there were in Scotland 17,593 insane persons of whom they had official cognisance In that number is included the inmates of training schools for imbecile children and of the criminal lunatic department of Perth prison. Of these 2563 were maintained from private sources, 14,979 by parochial rates, and 51 at the expense of the State. As the total number of the insane on Jan. 1st, 1906, was 17,450, an increase has taken place in the past year of 143.

HOUSE OF COMMONS.

WEDNESDAY, JULY 3RD.

Insanitary Dwellings in Ireland.

Answering Mr. O'SHAUGHNESSY, Mr BIRRELL said: The Housing of the Working Classes Act, 1890, confers full powers on local authorities in Ireland to take proceedings with the object of having insanitary dwellings put into proper condition and in the event of default to secure the demolition of the insanitary buildings. The local authorities have no power to enter into possession of such dwellings or areas and to retain the receipts of the property in order to pay for repairs and it is not proposed to undertake legislation with that end.

THURSDAY, JULY 4TH.

Tuberculosis in Ireland.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the recommendation of the medical superintendent officer of health of Belfast, Mr H W Bailie, that the coöperation of all the medical practitioners of the city should be invited in the voluntary notification of tuberculosis and that great advantages would result therefrom in regard to precautions dealing with tuberculous houses and areas, whether the deaths from tuberculosis in Ireland were over 12,000 per annum, or 16 per cent. of the total deaths registered, and that the number in Belfast was exceptionally high, and whether, in view of the importance of the subject and the unanimous sentiment amongst Irish medical men in favour of its being dealt with promptly and thoroughly he would put himself in communication with the local authorities in Belfast, Dublin, and the principal centres of the country, with a view to taking such measures as would tend to mitigate the ravages of this disease.—Mr BIRRELL replied: The attention of the Local Government Board has been called to the recommendation referred to in the first part of the question. The statements made in the second part of the question are substantially correct. The Local Government Board are constantly urging upon Irish local authorities the necessity for the full exercise of their powers under existing legislation with a view to checking the mortality from tuberculosis. With regard to the concluding part of the question I may say that I have already been in communication with the general council of the Irish county councils upon the subject of possible further legislation in this important matter and have promised to receive a deputation from the council on the subject in the coming autumn.

Report of the Medical Officer of Health of Portsmouth.

Mr BRAMSDON asked the President of the Local Government Board whether his attention had been called to statements in an official report of the medical officer of health of Portsmouth that during the past 12 months 67 diseased cows had been sold for human food at sums varying from 20*s* to 80*s* at certain country markets, and that the diseased meat of most of these cows had been disposed of in London, and, in the event of these statements being proved correct, what steps His Majesty's Government proposed to take to prevent such a state of affairs —Mr BRAMSDON further asked whether the attention of the right honourable gentleman had also been called to statements in an official report by the medical officer of health of Portsmouth to the effect that the milk from cows badly diseased with tuberculosis was systematically sold, and whether, taking into consideration the statement in the interim report of the Royal Commission on Human and Animal Tuberculosis to the effect that a considerable amount of disease and loss of life, especially amongst the young, must be attributed to the consumption of cow's milk containing tubercle bacilli, together with the returns of the Registrar-General, which showed that 10,000 children under five years easures intended to increase both the comfort and the urability of these structures. The exterior of one of the ouses at Wasta is seen in Fig. 36.

At Abu-Saad there is no room left to put up any new ouses for pilgrims; the four old houses existing there are apable of holding 80 pilgrims each, or 320 in all. At Wasta, n addition to the two old houses and the six large and three mall new houses just completed, the plan proposed provides or 13 new houses, of which nine would contain 80 pilgrims ach, one would contain 70, and two 60 each. There would hus be in all in Wasta 12 houses for 80 pilgrims each, one or 70, and eight for 60; or accommodation for 1510 persons. hese houses would be grouped in five cordons, as shown on he plan, capable of holding respectively 240, 630, 240, 180, nd 220 pilgrims. The four houses at Abu-Saad, it should ave been stated above, will each form a separate small ordon for 80 pilgrims; this is practically necessitated by he position they occupy, but fortunately, as statistics how, the majority (57·5 per cent.) of ships coming to his lazaret carry less than 80 pilgrims each. On Abu-Ali it is proposed to cut off the north end of the island y a double wire fencing, to the north of which will be onstructed the infectious diseases hospital, while to the outh there will be room for one or two cordons holding bout 650 or 700 pilgrims. Thus the maximum number of pilgrims that this lazaret can accommodate, so long as it is onfined to these three islands, will be about 2500, distributed as follows: Abu-Saad, 320; Wasta, 1510; Abu-Ali, say 670. At present it will be seen that only some 840 pilgrims can be lodged in stone houses. The remainder have to be put under tents. The tents belong to the Turkish Government and are usually sent down from Mecca to Jeddah when they are required at the lazaret.

The present drinking-water supply of this lazaret is provided by a distilling apparatus. This was put up last year in a building near the jetty on Abu-Saad which was formerly the disinfecting pavilion. The apparatus is of the "Weir" type. The total cost, including transport to the lazaret, was about £660 sterling. It is capable of producing 15 tons of fresh water in 24 hours. The machine was being put up when the Commission visited the lazaret and had not begun to work. During the season just completed it is said to have worked well and given satisfactory results.

When this lazaret was first brought into existence it was intended to use rain-water for the pilgrims. A large masonry reservoir was constructed by the side of each of the stone houses which have been described. But rain is extremely rare in these regions and it is said that these reservoirs have never held any water at all. The lazaret has consequently been dependent hitherto upon a small distilling apparatus mounted on the tug *Zulal* already described or on water from Jeddah. The distiller on the *Zulal* is capable of producing only three or three and a half tons of water per day, an insufficient quantity when the lazaret is anything like full. The Jeddah water is, as was shown in a previous article, of the very worst quality possible. Consequently there was abundant reason for putting up the new distilling apparatus.

The existing method of distributing the water through the lazaret was found to present many grave drawbacks. At Abu-Saad there is a cemented masonry reservoir of ten tons on the jetty and at Wasta there are two iron reservoirs on the sand by the side of the jetty. Twice a day the groups of pilgrims were allowed to leave their cordons in turn and come to these reservoirs where they filled their jugs or tins with the amount of water allotted to them (two and a half litres in the morning and the same quantity in the evening). It is obvious that such an arrangement infringes the principles of the complete isolation of each group from the other and of the thorough security of the central water-supply from contamination. It was bad enough at Abu-Saad where the reservoir has a tap; it was still worse at Wasta where the pilgrims dipped their vessels into the reservoirs themselves. It has now been decided to have five large galvanised iron central reservoirs of ten tons each, one at Abu Saad, three at Wasta, and one at Abu-Ali; from these the water will be conducted to each cordon in underground pipes and in each cordon there will be a tap under the control of an employee of the lazaret, where the pilgrims will take their water twice a day, as at present, but without leaving their cordons.

Salt water is supplied to the disinfecting pavilion in Abu-Saad by a pump which aspirates the water from the sea and distributes it to two small reservoirs of one and a half tons each. At present the salt water goes no further, but piping is now to be laid down which will conduct it to the latrines in the new hospital to be put up at Abu-Saad and also to those of the lodging for employees to be referred to later.

The latrines for pilgrims at this lazaret are situated at the end of long wooden jetties running out into the sea. It will be recalled that similar jetties exist at Camaran and that it was necessary to condemn roundly their use at that lazaret.[2] The conditions, however, at the three islands near Jeddah are different. There the tide does not run out a long way, leaving a wide expanse of sand and the latrines dry, as at Camaran. On the contrary, with comparatively short jetties it is possible to put up the latrines where there will always be water below them. Moreover, there are very strong currents which carry away the solids immediately and the sea swarms with fish which apparently devour them. Consequently the lazaret employees declare the existence of these latrine jetties at Abu-Saad and Wasta has hitherto never given rise to the highly unpleasant conditions which rendered their condemnation necessary at Camaran, nor indeed to any complaint of any kind. In view of the small area of the islands it is not only advantageous but almost necessary to continue the use of latrines at the end of jetties.

In place of the old wooden jetties several new ones consisting of wooden beams and planks supported on concrete and masonry piers have been put up during the past year, and several others are projected, so that in all there will be five such jetties at Abu-Saad, seven at Wasta, and one (or two) at Abu-Ali. In the new hospital at Abu-Saad and in the residences for the staff on that island it has been decided to put in water-closets with flushing cisterns and drains to the sea.

A very serious defect in this lazaret is the entire absence of proper hospital accommodation. Hitherto if any cases of illness occurred among the pilgrims they were treated either in an empty house for pilgrims (if there happened to be one empty) or in a tent, or very often in the cordon to which they belonged, without removing them from the healthy pilgrims. The Commission naturally condemns such an arrangement and urges the immediate construction of two hospitals, one for ordinary diseases, the other for infectious diseases.

The ordinary diseases hospital will be built on Abu-Saad on a roughly triagular area near the southern end of the island. The plan proposed for this hospital is furnished in the report of the Commission. It provides for two wards capable of holding some 12 patients, a bacteriological laboratory, pharmacy, bath-room, two water-closets, and a room for the attendants.

In the plan of the island of Wasta (Plan V.) a space has been left for the future construction of a second hospital for ordinary diseases, so as to avoid the transport of the sick from this island to Abu-Saad. Finally, the infectious diseases hospital will be built at the northern end of the Abu-Ali island; it will be capable of holding 12 patients and will be provided with the usual annexes.

The staff of this lazaret consists of the following: one permanent medical officer, to whom during the height of the pilgrim season a second, and even a third, may be added; one clerk; one "étuviste" to work the disinfecting stoves; a head-disinfector and two disinfectors (increased in case of necessity); a head-guard and four permanent guards; and a number of temporary guards varying with the number of pilgrims interned in the lazaret. In addition there are two "mécaniciens," a first and second, who are in charge of the tug *Zulal*, the small launch, and the distilling apparatus and disinfecting stoves; a pilot, two sailors, and two stokers on board the tug; and four boatmen for the sailing boat. To lodge all these employees there exist a small residence on the island of Abu-Saad, another one on Wasta, and four rooms in the old disinfecting pavilion, by the side of the central chamber in which the new distilling apparatus has been put up. The residence on Wasta is a two-storeyed building, with two rooms and a vestibule on each floor. The Commission found it in an extremely bad state of repair and practically uninhabitable. It will therefore be demolished and another building—the plan of which is furnished in the Commission's report—will be put up instead, on a site near to the landing jetty.

The residence on Abu-Saad, which is shown in Fig. 37, is

Hospital for Sick Children, Great Ormond-street, London, W.C. House Physician, House Surgeon, Assistant Casualty Officer.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Kensington General Hospital, Earl's-court, London, S.W.—Junior Resident Medical Officer. Salary £40 per annum, with board, washing, and residence.

Lenzie, Woodilee Asylum.—Junior Assistant Medical Officer. Salary £125 per annum, with board, washing, &c.

buildings in Edmund-street to the hall. The spectacle inside the hall was brilliant, the decorations blending charmingly with the pretty dresses of the ladies and the varied gowns of the teachers and graduates. After the Vice-Chancellor (Alderman C. G. Beale) declared the Congregation open little or nothing was heard except the noises made by the students as they welcomed and congratulated the various recipients of degrees. No one seemed to mind the noise, which rose to crescendo whenever a particular favourite approached the rostrum, and indeed it mattered little, for everyone knows the formula of presentation and that of reception, and there were no speeches. Professor Sir Edward Elgar, who was presented for the degree of Master of Arts, received a great ovation, and Professor Kirkaldy, who was obviously also a favourite of the students, received the degree of Master of Commerce. 29 graduates in arts were presented by Professor Fiedler, 43 graduates in science by Professor Poynting, 12 graduates in medicine by Professor H. Gilbert Barling, and one in commerce by Professor Ashley. Mr. Sidney S. Dawson, F.C.A., has been appointed to the chair of Accounting, which became vacant by Professor Dicksie's resignation, and Mr. A. W. Wellings, B.D.S., has been elected lecturer in Dental Histology and Pathology in the place of Dr. H. P. Pickerill, who has accepted the appointment of director of the Dental School of New Zealand.

Annual Report of the Medical Officer.

With the exception of two points Dr. J. Robertson's report of he health of the city during 1906 is very satisfactory but the nfant mortality and the death-rate from zymotic disease were not what could be desired, for the former was 163 per 1000 and the latter 2·78 per 1000. So far as the infant mortality s concerned it may be allowed that the summer of 1906 was, o a certain extent, exceptional and no doubt the death-rate, igh as it was, would have been much greater under similar conditions a few years ago; we may, therefore, hope for still better results in the future but we shall only get the better results when the mothers understand their duties. It has been frequently urged that the milk-supply is mainly the cause of excessive infant mortality but those who have seized upon that one point will have to reconsider their position, so far as deaths from diarrhœa are concerned, for, as Dr. Robertson points out, with respect to Birmingham, all the deaths occur in one moiety of the population and the other is practically immune, and the milk-supply is practically the same. The exceptional summer of 1906 does not account, however, for the ncrease of the zymotic death-rate and the cause of the rise from 1·94 in 1905 to 2·78 is not at present readily explainable on any definite grounds. With the exception, however, of the two sets of unsatisfactory conditions above mentioned the general health of the city during 1906 was extremely good. There was no small-pox, the deaths from typhoid fever were very few, and the total death-rate only amounted to 16·8 per 1000, or very slightly higher than the record year 1905, when it was only 16·1 per 1000. The birth-rate varies in the different wards from 18·6 to 37·3 per 1000 and averages 29·3 per 1000, as against 29·2 in 1905. On the whole, therefore, the city compares favourably with many other large towns and as the improvements which have been initiated begin to tell we shall gradually occupy a more and more enviable position in the general mortality returns.

Birmingham Lunatic Asylums and the Cost of Pauper Lunatics.

From the annual report of the asylums committee it appears that the number of patients in the asylums has been reduced during the year from 2029 to 1998. At first sight this may appear to be satisfactory but further consideration will diminish any congratulatory thoughts for, according to the report, the discharges from the asylums include 199 recovered, 39 relieved, and 74 not improved, and a little consideration will show that many of the so-called recovered will return at a future day and both they and the relieved will in the meantime beget children who, even in the most favourable circumstances, will help to swell the record of the lunatics of future years. It would be costly in the first instance to prevent this, but it would be economical eventually, and though it would inflict some hardship in a number of cases it would be good for the race as a whole, and some time it will have to be done. In the meantime the ratepayer will be glad to know that we are to pay a little less for our pauper lunatics, the price per head being reduced from 11*s*. 11*d*. to 10*s*. 6*d*. per week.

Exhibition of Hand Loom Weaving by Crippled Girls.

Some five years ago a school of hand-loom weaving was established in association with the Birmingham Crippled Children's Guild, the object being to provide some crippled girls with a means of making a living. It was commenced on a small scale but it was soon seen that the scheme was capable of expansion, and last year the school was moved to more commodious premises. At first it was not a financial success but now it pays its way on sound commercial lines both as regards the sale of its work and the pay of the workers. It utilises ten looms and gives congenial employment to 12 crippled girls, and it is rapidly establishing an excellent reputation which is being won in open competition, for at the exhibition held at the Albert Hall in London this year 29 of the 30 exhibits sent by the school secured awards. Although the work done pays working expenses the profit is not at present sufficient to pay off expenses incurred in establishment and more money is needed for the provision of some new English looms. It is to be hoped that this will soon be provided, for an institution which enables afflicted girls to earn a living by work which is not beyond their restricted capabilities is surely worthy of support. Mrs. Kirkaldy, the president, and the members of the committee working with her wish to develop the enterprise on coöperative principles and they are anxious in the first instance to clear off the debt. Some of the materials shown at the recent exhibition at Queen's College were excellent examples of their class and those who wish to utilise artistic and durable materials cannot do better than communicate with the school authorities.

St. John Ambulance Brigade: Birmingham Corps.

The recent inspection of the Birmingham corps of the St. John Ambulance Brigade was held in the Botanical Gardens and in spite of the very bad weather passed off successfully. The total number at the parade, including two companies of nurses, was 180. In the evening, after the inspection, Colonel Elliston, the inspector, distributed the certificates and complimented the brigade upon the way in which it had turned out and upon the character of the work which it had done during the afternoon. He also expressed the hope that the brigade would respond heartily to the offer that they should serve as a reserve to the Army Medical Corps under the new scheme.

Wolverhampton Annual Health Report.

Though Wolverhampton may not seem a very desirable place to live in to the passing stranger, more especially if he passes only along the railway lines, nevertheless the annual report of Dr. H. Malet shows that the health of the borough compares very favourably with the health of other large industrial centres. During 1906 the total death-rate was only 14·8 per 1000 and the birth-rate was 27·5 per 1000. Small-pox was absent and typhoid fever was rare, but measles and diphtheria were more than usually prevalent.

July 9th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday and Saturday Funds: First interim Distribution of £10,000.

THE distribution committee of the above-named funds met at the town hall on July 1st, when the treasurer announced that an interim distribution would be made to the various charities of £10,000 on the same basis as last year. The Royal Infirmary will receive £2125, the Royal Southern Hospital £1475, the David Lewis Northern Hospital £1275, and the Stanley Hospital £800. The other charities will receive smaller amounts proportionate to the number of beds in each. The honorary treasurer said that with regard to the guarantee of the 10 per cent. gift by Alderman Cohen and his ten friends the Sunday Fund so far showed an increase over last year of £882. The Saturday Fund is not expected to be any less than last year, so that the committee anticipated asking the 11 guarantors of 10 per cent. for £88 each, or £968 altogether.

The Liverpool Water-supply.

In his annual report the water engineer of the Liverpool corporation stated that Liverpool is now supplying more than 1,000,000 people with water and the sources are so abundant that to add Birkenhead to the list could not

SIMPLE METHOD OF URANALYSIS WANTED.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me where I can find a description of a *simple* method for the approximate quantitative estimation in urine of (1) phosphates; inorganic sulphates; and (3) organic sulphates. The methods and apparatus usually described I consider to be too elaborate for the practitioner.

I am, Sirs, yours faithfully

July 8th, 1907. S. W.

THE VERNIX CASEOSA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me information bearing on the theory that the vernix caseosa is caused by sexual connexion during pregnancy? I should be glad to know if this substance has any physiological function or whether there is any proof of its being harmful to the child.

I am, Sirs, yours faithfully,

ROBERT M. RIGGALL, L.R.C.P. & S. Edin., L.F.P. & S. Glasg.

Hathersage, viâ Sheffield, June 27th, 1907.

A NEW BEDSIDE MAT.

WE have received from Dr. Alexander Ambrose, of Loughton, Essex, a sample of his "non slip" mat for bedside use, devised to obviate the slipperiness of the polished floors so common in hospitals, asylums, and similar institutions. The upper surface resembles that of a piece of stout stair carpet 4 feet 6 inches long and 23 inches wide, while the under side is coated with a thin layer of a composition which, without being sticky in the slightest degree, gives a good foothold on the smoothest floor. In respect of the tendency to glide on a polished surface there is quite a contrast between the two sides of the mat. It is evidently well fitted to serve the purpose for which it is intended.

WANTED—A MEDICAL HOME IN FRANCE.

To the Editors of THE LANCET.

SIRS,—Could any of your readers tell me if there is a good medical establishment for the treatment of nervous disease at a place called Vernet sur la Seine, near Paris? Are there any French medical men who take paying guests for treatment near Biarritz or in any quiet, nice town in France? Are there any medical homes near Passy or Neuilly?

I am, Sirs, yours faithfully,

July 5th, 1907. MATER.

POST SCARLATINAL BALDNESS.

To the Editors of THE LANCET.

SIRS,—A woman, aged 60 years, who contracted scarlet fever nearly four months ago, has been losing her hair (a very good crop before the illness) ever since. Can any of your readers suggest any application to arrest this loss, or any treatment likely to be beneficial, as baldness is threatened?

I am, Sirs, yours faithfully,

July 9th, 1907. SENEX.

◆

M.B. Lond.—The Workmen's Compensation Act gives power to the Secretary of State to appoint legally qualified practitioners as medical referees; application for the office should accordingly be made to him. We may remind our correspondent that "where a medical referee has been employed as a medical practitioner in connexion with any case by, or on behalf of, an employer or workman, or by insurers interested, he shall not act as medical referee in that case." A surgeon certifying a case under the Factories Act will accordingly be ineligible to act as referee in that case.

Dubiens.—It is, we believe, usual and certainly very advisable that partnership agreements between medical men should contain stipulations for fair arrangements in the case of absence of either partner on account of sickness or accident. We have never heard of a case where a sick partner having secured the services of a competent locum-tenent was made the defendant in an action for damages brought against him by the other partner.

I. R.—It might be as well for our correspondent to communicate with the National Association for the Prevention o Consumption, 20, Hanover-square, London, W.

Health is referred to an annotation in THE LANCET of July 6th, page 40, entitled, "An Act to Prevent Procreation of Unfit Persons."

Lux Veritatis.—We can understand the difficulty of the insurance companies and think that their attitude is justifiable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received.—*Townsville Daily Bulletin* (*Queensland, Australia*), *Manchester Guardian, Chester Chronicle, Hastings and St. Leonards Observer, The North Star* (*Darlington*), *Daily Mail, Birmingham Gazette, Notts Guardian, Child's Guardian, Daily Express Advertising World, Westminster Gazette, Bristol Times, Manchester Evening Chronicle, Herald of Health, The Trib Siam Free Press, Newcastle Chronicle, Eastern Morning News, Lin Echo, Tewkesbury Record, South Wales Echo, Glasgow Evening Ti East Anglian Daily Times, Daily Graphic, Yorkshire Daily P Sheffield Independent.*

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Channel Fleet in the Firth of Forth.

THE presence of the Channel Fleet in the Firth of Forth has been taken advantage of by the Royal College of Physicians of Edinburgh to entertain the medical officers of the fleet. The entertainment took the form of a luncheon given on July 6th, in the hall of the College, presided over by the President of the College, Dr. C. E. Underhill. Owing to the shortness of the notice many of the Fellows of the College who might have been present were unavoidably absent.

Centenary of the Royal Edinburgh Asylum.

The Royal Edinburgh Asylum completes the 100th year of its existence, having received its Royal Charter on May 2nd, 1807. In view of this invitations have been issued to a garden party to be held at Craig House on July 12th. The east house was opened for patients on July 9th, 1813, and a west house was determined on in 1837. The first physician-superintendent was Dr. Mackinnon appointed in 1840. The following year it became a Royal asylum, Queen Victoria becoming its patron. In 1846 Dr. S. Rae was appointed physician-superintendent. In 1873 he was succeeded by Dr. T. S. Clouston who still occupies the position with undiminished vigour and whose administrative and clinical abilities have so largely contributed to give the asylum the distinguished position which it occupies.

The Discussion on General Paralysis at the Edinburgh Medico-Chirurgical Society.

As will be seen from the report of the meeting of this society held on July 3rd Dr. W. Ford Robertson and Dr. G. D. McRae have carried their investigations into general paralysis an important step further. Unfortunately, there was no attempt on the part of the officials of the society to ensure a full discussion of this work. The communication was preceded by an interesting surgical paper which gave rise to some discussion which would have been added to had there been time. Short as the discussion was it encroached upon the time allowable for the more important paper which followed. The discussion, it will be seen, was confined to alienists, while not a general physician, pathologist, or bacteriologist took part in it. The subject is so very important that it is a matter of great regret that it was not fully and freely threshed out. Such a discussion might have been invaluable to the investigators themselves.

School of Medicine of the Royal Colleges, Edinburgh.

At a meeting of the governing board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary and registrar, Mr. R. N. Ramsay, reported that the number of students attending the school during the winter session, 1906-07, was 1048, and during the summer session, 1907, the number was 961.

Kingseat Asylum.

The estimate of the maintenance account issued in connexion with the City District Lunacy Board for the year ending May 15th next shows a total of £11,556, compared with £10,380 last year. The account is based on the average number of patients in Kingseat Asylum for the year ending May 15th last being 414, and the probable number of admissions for the year ending May 15th next being 86, giving a total of 500, less 80 as the probable number of deaths and discharges during the year, and an average number of 10 boarded out, reducing the average number to 410, or with 70 officials and attendants added to 480. From the estimated expenditure of £11,556 falls to be deducted the balance of £485 at the credit of the account for the past year, leaving the sum to be provided at £11,070. The estimated average cost per head per annum on 410 inmates is £27. Last year the receipts were made up as follows: balance at credit of close of last account £665; board of patients, £10,358; and farm and garden, £3403; making with receipts not falling under the above heads a total of £14,439. The payments were: maintenance of patients and expenses, £10,331; furnishings and furniture, £267; farm and garden, £3303; and balance at credit at May 15th last, £485. At a committee meeting of the Aberdeen District Lunacy Board it was agreed that the cost for maintenance of inmates of Kingseat Asylum should be fixed at £27 per annum for the current year in place of £25 last year. A "vidimus" was submitted showing the sum to be raised by assessment under the heading of "providing accounts" for Kingseat Asylum to be £10,000—an increase of about £500 on the sum required for last year, and it was agreed to intimate to the General Board of Lunacy that this amount would have to be rated for. The present rate is 1·735*d.* both to owners and occupants and the increase will be a mere fraction. This rate is levied by the town council.

Dundee Sanatorium for Consumptives.

At the annual meeting of the supporters of the Dundee Sanatorium it was reported that the average number of patients in the sanatorium during the year was 36. The average sum received per patient throughout the year was one guinea per week, while the cost to the institution was 38*s.* The chairman stated that the accounts had closed with a deficit of £670, which had, however, been entirely cleared off by an anonymous London friend. The deficit was due to the fact that the cost per patient was much in excess of the average sum received from local patients whom the committee felt it was bound to admit to the benefits of the institution.

Aberdeen University Anatomical and Anthropometrical Society.

A meeting of this society was held in the anatomical department of Marischal College on July 6th, Professor R. W. Reid presiding. Intimation was made by the chairman of the presentation to the museum of a short cist by Mr. W. Bean Moir of Scotstown. Dr. A. Low gave a short description of the cist and its contents. Papers on anatomical subjects were read by Mr. J. Fettes and Mr. S. G. Trail. The following office-bearers were appointed for the ensuing year:—President: Professor R. W. Reid. Vice-Presidents: Dr. Alexander Low, Dr. R. W. Salmond, and Mr. James Watt. Secretary: Mr. N. J. Calder. Recording secretary: Mr. J. W. Fiddes. Treasurer: Mr. R. Richards.

The Montrose Asylum Tragedy: the Official Inquiry.

The result of the inquiry by the house committee of the Montrose Asylum into the circumstances connected with the recent tragedy was submitted to the managers for their approval at a meeting held last week. The report stated that the committee had carefully inspected the scene of the tragedy and had taken the evidence of Dr. J. G. Havelock and various other officials. The committee was of opinion that no blame could be attached to any of the officials. It was clearly proved that Simpson was a well-conducted and peaceable inmate and that he was in feeble health at the time of the fatal occurrence. Searching inquiry was also made into the management of the male part of the hospital during the night, and the committee recommends: (1) that instead of one night attendant there should be two, with the view of giving increased inspection to the various wards in the hospital; (2) that another sub matron should be appointed to supervise the night attendants in the whole of the various buildings; and (3) that night attendants should not be allowed to undertake any work during the day without the sanction of the medical superintendent. In the course of the inquiry it was elicited that the night attendant had been working on a farm for a number of hours every forenoon. The report was unanimously approved of by the managers.

July 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Rainfall in June in Ulster.

JUNE has been the wettest month, it is said, for 20 years, rain falling on 26 days to the amount of 5·63 inches. In June, 1906, the rainfall was only 1·23 inches, and in the same year up to the end of June 15·43 inches fell, while this year, for the same period, 20·62 inches have fallen. In 1889 the rainfall in June was only 0·3 of an inch. An inch of water represents 100 tons per acre.

Cerebro-spinal Fever in Belfast.

During the week ending June 29th 11 cases of "spotted fever" were notified, as against 16 in the previous week. Since the meeting of the public health committee on June 27th up to the next meeting on July 4th only five cases

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

gummatous infiltrations dried up. The effect of this treatment was, just as in the case of mercurial treatment, different in individual patients, showing itself sometimes quickly and sometimes slowly. In one case only no effect at all was observed, so that a course of mercury had to be given. It was remarkable that the spirochætæ continued to be present in the cases treated successfully by atoxyl.—The atoxyl treatment of syphilis was also discussed by Professor Lesser before a meeting of the Berlin Society of Internal Medicine. He first spoke against excision of the primary chancre and against the administration of mercury previously to the appearance of the secondary symptoms, both of these procedures being inadvisable in his opinion. He recommended the intermittent treatment according to Fournier's method during the first years after the infection. According to him the spirochætæ were not destroyed by mercury, although their virulence became diminished. Injections of atoxyl in large doses (six grammes have been administered) had a beneficial effect. The action of atoxyl was especially remarkable in "galloping" syphilis, where an improvement was obtained much more quickly than by mercury. He had also observed undesirable symptoms, especially albuminuria, so that caution in the use of the drug was absolutely necessary.

The Prevention of Tuberculosis.

The annual conferences of the German committee for the prevention of tuberculosis and of the medical men holding appointments at sanatoriums connected with the anti-tuberculous movement were held at Berlin on May 20th and on May 24th and 25th respectively. Count Posadowsky presided over the meeting of the committee and Professor Fraenkel over that of the medical men. At the meeting of the committee Herr Kehl read a paper on the Struggle against Tuberculosis in the Country, explaining the reasons why the mortality of tuberculosis in the country exceeded the average mortality of the disease. He strongly recommended the establishment of small hospitals in rural districts where these institutions were evidently not numerous enough to meet the wants of the population. In addition to the hospitals he recommended that nurses brought up in the country and trained for a shorter period than those working in the towns should be appointed in rural districts. There ought to be courses of instruction for nurses and lectures for ladies who might eventually desire to act as honorary nurses in case of need, and a system of dispensaries ought to be established all over the country districts which hitherto had been left somewhat in the background as compared with the amount of work done for the towns. Another subject discussed in the meeting concerned the sanatoriums which were recently so unfavourably criticised, as reported in THE LANCET of May 11th, 1907, page 1328. All the speakers agreed that these attacks were quite unfounded. In the meeting of medical men addresses were delivered on the genesis of pulmonary tuberculosis from the bronchial glands through the lymphatics, and radiograms were shown in which the progress of tuberculous processes was seen. The principal subject of discussion was the tuberculin treatment. It was generally agreed that good results were obtained, especially by the old tuberculin of Professor Robert Koch; whilst some of the speakers preferred Marmorek's serum. Dr. Neissen of Stettin recommended the administration of an emulsion of tubercle bacilli in severe cases. The tuberculin treatment must of course be combined with hygienic and dietetic measures. Prejudicial effects due to the administration of tuberculin were not observed. No trustworthy report could be obtained on the effect of Professor von Behring's tulase, as he distributed the compound only under the condition that reports were to be made exclusively to himself.

Bad Brückenau.

The Royal State Ministry of Finance, which has charge of the Royal Bavarian Baths, invited the medical men of Munich to pay a visit of inspection to the Royal Mineral Baths of Kissingen and Brückenau. These gentlemen therefore travelled on June 24th in a special train placed at their disposal to Kissingen and thence by automobile to Bad Brückenau. They especially visited the Wernarzer, Stahl, and Sinnberger springs which are renowned for their healing properties and entirely approved of the accommodation provided there; not a small amount of their praise was expended on the carbonic acid baths which are made as efficient as possible. In the afternoon a dinner was given by Kgl. Kommerzienrat Roth to the medical men and was attended by His Excellency Herr Kgl. Staatsminister von Pfaff and by other Government officials, altogether about 100 persons. Just after 5 o'clock in the evening the medical men travelled back to Munich by special train after expressing the greatest satisfaction with their visit to Bad Brückenau.

July 8th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

Appointment of an Englishman as a University Professor in Sweden.

IT would seem that some dissatisfaction has been aroused in Swedish medical circles on account of the Medical Faculty of the University in Lund having decided to offer the recently established chair of pharmacology to a foreigner, Mr. Ernst Overton, Ph.D. Mr. Overton is by birth an Englishman but he completed his academical career in Zürich, where for some time he lectured on biology. His latest appointment was as assistant to the famous physiologist, Professor von Frey, in Würzburg. The fact that no Swedish pharmacologist was available at the time in question forced the Medical Faculty of the University of Lund to look abroad for a suitable man, and considering the excellent scientific qualifications of Mr. Overton, there can be no doubt that the choice has been very fortunate. The objectors to his appointment, however, lay stress on the circumstance that he has not passed any medical examination, as also on the regulation providing that foreigners appointed to chairs in the Swedish universities must profess the pure evangelical doctrine in religion. The first objection will undoubtedly form no serious obstacle as Mr. Overton's work in biology and physiology is an excellent preparation for the modern teaching of pharmacology; and the second will probably be met in a way suggested by the Chancellor of the University, Bishop Billing—namely, that the question be left undecided until Mr. Overton has acquired Swedish nationality when the difficulty will cease to exist.

The Treatment of Tuberculous Laryngitis.

Dr. S. Bang, the medical director of the Tuberculosis Sanatorium of Silkeborg in Denmark, has constructed an apparatus for the treatment of tuberculous laryngitis by means of the electric light. Five or six years ago, when a member of the staff of the Finsen Light Institute, he made the preliminary experiments that have resulted in the simple and efficient apparatus which he has now been using for the last three years. As it is necessary to employ only "cold light" the source of light that has been selected is the arc lamp with iron electrodes, originally devised by Dr. Bang. The rays of this lamp are received by a rectangular quartz prism placed at the narrow end of a metal funnel which the patient takes into his mouth and from the hypotenuse of this prism the rays are totally reflected into the larynx. As with a current of 10 or 12 ampères about two minutes suffice to produce a very strong typical light reaction on the interior of the larynx, the surgeon can manipulate the apparatus during the whole exposure and can make sure that the rays really reach the diseased parts of the larynx. Dr. Bang thinks that the method will prove useful only in those cases in which it is possible to direct the reflected rays at a right angle to the affected area.

(FROM OUR OWN CORRESPONDENT.)

Diagnostic Injection of Tuberculin in an Infant.

AS medical men very seldom have an opportunity of witnessing the infection of a patient with tuberculosis and the subsequent development of the disease the following case, shown by Dr. von Perquet at a meeting of the Gesellschaft der Aerzte, possesses considerable interest. A child of five weeks of age was brought to him with eczema of the right cheek. This soon improved but an ulcer remained for some time, the child began to lose weight, and the family history revealed the influence of pulmonary tuberculosis. Three weeks later the glands of the neck became markedly enlarged, bronchitis followed, and when the child was 16 ministration then continued by means of ether and the Rendle's mask. In older subjects the ordinary methods for obtaining ether anæsthesia will be applicable. For similar reasons to those which I have here given ether is specially indicated for short rectal operations.

In a considerable proportion of general surgical cases I find that the O.E. mixture produces better results than any other anæsthetic with which I am acquainted. Although a great deal has been said against anæsthetic mixtures I must confess that I have never met with any clinical phenomena to support the adverse opinion which many hold. The O.E. mixture seems to produce rather better results than the A.O.E. mixture, probably because the patient is spared the process of eliminating the alcohol which he necessarily inhales when the latter mixture is used. It has in my hands answered better than any other anæsthetic for obtaining what may be termed the fine adjustments in anæsthetisation. As I shall presently point out, there is in the vast majority of cases a neutral borderland in the realm of general surgical anæsthesia, and if this particular borderland can be reached and retained safe and quiet anæsthesia may be relied upon. In a large number of abdominal cases and in most patients over 60 years of age this mixture answers admirably. Much depends, however, upon the actual means employed for administering the O.E. mixture. Rendle's inhaler and its numerous modifications fail to supply a vapour of equable strength; they not unfrequently allow the liquid anæsthetic to run out of the inhaler and thus to redden or blister the face, whilst they are liable, if continuously applied, to produce over-dosage.

FIG. 1.

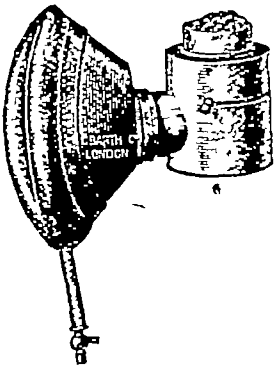

FIG. 2.

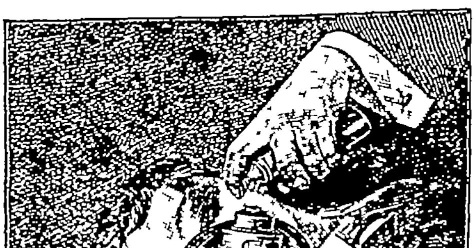

Having used the inhaler here figured for about three years I am able to speak with confidence as to its merits.[1] It consists of a simple metal cylinder capable of holding a sponge and surmounted by a wide circular opening through which the anæsthetic is poured (Fig. 2). This air opening is so large that it is difficult, if not impossible, to administer a dangerously high vapour-percentage. The inhaler errs on the side of safety, for it is necessary, when anæsthetising comparatively insusceptible patients, to temporarily and loosely cover the circular air-opening with the hand. In ordinary cases the sponge may be kept thoroughly wet, any excess of the anæsthetic mixture simply running through the lower part of the cylinder upon the hand of the administrator. It is important that the sponge should be coarse and that it should only loosely fit the metal cylinder.

2. THE MAINTENANCE OF UNEMBARRASSED, AND PARTICULARLY OF UNOBSTRUCTED, RESPIRATION DURING AND AFTER THE ADMINISTRATION.

It is often supposed that in administering an anæsthetic the function of respiration will remain unimpaired provided the agent in use be not pushed to a toxic degree. This, however, is a grave error, for breathing far more commonly comes to a standstill from causes other than overdosage itself. There are, in fact, four distinct modes of respiratory arrest during general surgical anæsthesia. Thus breathing may cease (*a*) from the presence of muscular spasm or some other condition *within* the air-passages, causing occlusion of those passages; (*b*) from some *external* agency preventing lung expansion; (*c*) from a diminution or arrest of the blood-supply to the respiratory centres; and (*d*) from the toxic effect of the anæsthetic upon those centres. I need not here specifically enumerate the various immediate causes of respiratory embarrassment and failure; they may all be arranged under these four headings. What I am anxious to point out to you now is the paramount importance of maintaining a free air-way in order that the nervous energy which is available for working the respiratory pump may have its full play and produce lung expansion and contraction, thus insuring efficient pulmonary circulation and blood aeration.

One of the most frequent causes of difficulty in inducing and maintaining anæsthesia is the presence, before the administration, of partial or complete nasal obstruction. The anæsthetist should therefore particularly notice whether the patient has a so-called nasal intonation and if it is obvious that the nasal channels are inadequate a mouth prop should be placed between the teeth. Another important factor in determining the presence or absence of difficulties during anæsthetisation is the "bite" of the patient. Given a slight degree of nasal obstruction, good teeth, and a somewhat ill-developed and under-hung lower jaw, with considerable space, antero-posteriorly, between the upper and lower incisors, respiratory difficulties will almost certainly arise unless special precautions be taken. Whenever practicable oral breathing should be secured and maintained in preference to nasal breathing, for the latter is often inadequate, retarding the onset of anæsthesia and leading to hyperpnœa, venous engorgement, and abdominal rigidity. It is often possible, by securing oral in place of nasal breathing, to change completely, both literally and figuratively, the complexion of the case. Free oral breathing is particularly desirable in emphysematous and other subjects who display breathlessness before anæsthetisation. It is not always an easy matter, however, to obtain oral breathing, owing to the natural tendency for the tongue and palate to remain in apposition. The insertion of a mouth-prop or gag by no means necessarily ensures an oral air-way; and if this form of breathing be desired it may be necessary, especially in muscular and obese subjects, to adopt some simple means of separating the tongue from the palate. Even at the commencement of inhalation, when the patient is conscious, oral breathing has advantages over nasal, for not only does it ensure a free and continuous interchange between the gaseous contents of the lungs and the anæsthetic gas or vapour, but it largely prevents those suffocative sensations which sometimes distress and alarm patients.

I cannot too strongly urge upon you to make yourselves absolutely certain that respiration is being freely performed during anæsthetisation. When I tell you that even the most experienced anæsthetist may occasionally fail to notice that the air-way has become noiselessly occluded you will see that it is not always an easy matter to be sure that air is entering and leaving the chest. The anæsthetist should either hear or feel every respiration. Except when a bag inhaler is in use visual observation is valueless, for, as you are doubtless aware, abdominal and thoracic movements may continue for a time after complete occlusion of the airway. Stertor and stridor always indicate a tendency towards occlusion and they should not be permitted to become too pronounced. Whilst there is no objection to the presence of gathered up in subterranean conduits for final distribution. At present all the reservoirs are well filled with water in consequence of the late frequent rains. As a rule, not all the taps are working at a time. Of the 60 taps, for instance, supplying Pera with drinkable water only 25 are opened. The supply is, however, perfectly sufficient for the needs of the population. The quality of the water is not always of a high standard of purity. On several occasions mical and microscopical analyses have been made with atisfactory results. It has been found that the distant rces especially are frequently contaminated. Some time a special commission was instituted for the purpose of estigating the matter, so important for the health and ll-being of the general public.

Regulations Concerning the Sale of Fish.

The municipality of Constantinople has considered and epted the following proposals concerning the sale of fish the fish markets submitted by the commission on public giene. The measures, which, if properly executed, will ove of great benefit to the general health of the popula m, are as follows: 1. Fish must henceforward never be posed for sale in the open street in receptacles of doubtful eanliness. 2. Fish must be sold only in shops paved and ssellated with marble (which is so cheap in the East) or ith plaques of the so-called Malta stone. 3. The fish must washed and kept fresh for consumption by a special wire stem devised by the commission on public hygiene. 4. The unicipal inspectors will visit the fish shops every day and ill confiscate and throw into the sea any fish of doubtful eshness, inflicting at the same time severe punishments on ontraveners. The municipality has also decided to erect pacious fish markets in the principal quarters of the apital as well as in some suburbs and in Cadikeuy (the ncient Chalcedon) on the Asiatic shore.

Miscellaneous Notes.

Butter, whether of native origin or imported from other ountries, will henceforward be submitted to a strict hemical and microscopical examination at all the custom ouses, as it has been found almost always to be adulterated. —The large population of Aleppo will be provided with analisation works and good drinkable water from the eservoir near Heilani. A "mazbata" has been signed by Nazim Pasha and submitted to the Sublime Porte.—From the mortality returns of last week it appears that no case of cerebro-spinal meningitis occurred anywhere in Constantinople or its suburbs. Scarlet fever, however, is still raging in some districts on the Golden Horn.

July 2nd.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Reduction in Plague Mortality.

THE recrudescence of plague this year, the severest which India has experienced, has during the past few weeks rapidly abated. At the end of May 52,098 deaths in one week were recorded but a rapid drop has brought the mortality during the past week to less than 30,000. The decline is general but the chief centres are still in the Punjab and the United Provinces. The disease has sunk into comparative insignificance in the Bombay Presidency where formerly it was so extensive and so virulent.

A Dangerous Plague Scare in the Punjab.

A plague scare of a serious character has recently occurred in the Punjab. Two men were charged with having circulated false reports with intent to cause alarm to the public to the effect that plague was being widely spread through the instrumentality of agents of the Government who were employed in poisoning wells and streams with plague germs. One man at a public meeting stated that plague was in reality non-existent but that the Government was putting poison into wells and streams in order to kill off the surplus population. About the same time the people of the district were thrown into a wild state of excitement by the finding of some balls of flour or similar substance in various tanks and fountains which was the work of an accomplice. The chief culprit was sentenced to two years' rigorous imprisonment and the accomplice to 18 months.

Cholera in Kashmir.

In addition to plague Kashmir has been experiencing a severe epidemic of cholera. For the week ending June 10th no less than 2293 cases and 1315 deaths were reported.

The Practice of "Sati."

The practice of sati still survives in some parts of India though the cases reported are few and far between. Though prohibited by law the practice is apparently upheld even by educated Indians. In a Calcutta native paper there was recently given an account of a case and the editorial article was couched in the most approving tones. A Hindu in bad health went to Puri and died there. His wife when she heard of his death poisoned herself with opium, but before taking this course she wrote a note to her brother: "Don't grieve for me, brother. I follow him to whom I was intrusted by my parents." Satis by poison, known as "cold" satis or "white" satis, are far more common in India, particularly in Bengal, than is generally believed. It is argued that there is something pathetic and noble in the attitude of a wife who refuses to outlive her husband. The writer goes on to say: "Before the law interfered the burning alive of widows was considered obligatory by certain castes, and in view of the opinions expressed by educated Bengali gentlemen the question arises whether sati would not be introduced as one of the consequences of swaraj." I may add that this swaraj is a sort of reaction to old Indian ways and traditions as against the adoption of anything belonging to Western civilisation.

The Grant Medical College, Bombay.

The annual report of the Grant Medical College, Bombay, for the year 1906–07 states that the new M.B., B.S. degrees were passed by the senate of the university and sanctioned by the Government during the year, and the courses of study for these degrees have been begun at the college since January last. At the examinations for the diploma of L.M. and S. in June and November, 1906, there were 195 candidates, of whom 55 passed; six of the successful candidates were females. For the degree of M.D. there was one candidate, and he was successful. The total number of students is 638, including 100 Christians, 260 Hindus, 252 Parsis, 21 Mahomedans, and five Jews. A minor chair in bacteriology, to which Dr. N. F. Surveyor has been appointed, and two additional tutorships, one in pathology and the other in anatomy, have been sanctioned by Government. Lady Moore's bequest of £2000 has been utilised in constructing an operation theatre in connexion with the Sir Jamsetji Jeejeebhoy Hospital to be named the Sir William Moore operating theatre. The foundation stone of this theatre was laid by Lord Lamington, Governor of Bombay, in September, 1906, with Masonic rites. On the same day Lord Lamington also laid the foundation stone of the Sir Cowasji Jehangir Ophthalmic Hospital extension, to which Sir Cowasji Jehangir has contributed a munificent donation of 30,000 rupees.

June 20th.

THE PREVENTION OF CRUELTY TO CHILDREN.—On July 4th a meeting was held at Terry's Theatre, Strand, W.C., with the object of forming a committee for the Strand district to work on behalf of the National Society for the Prevention of Cruelty to Children in connexion with the Westminster branch. Colonel Clifford-Probyn, L.C.C., presided, and was supported by, among others, Mr. Edward Terry and Mrs. Terry, the Rev. J. H. S. Pennington and Mrs. Pennington, and Mr. R. J. Parr, director of the society. Mr. Parr pointed out that the objects of the society were to prevent the public and private wrongs of children and the corruption of their morals, and to enforce the laws which have been made for their protection. Last year the society dealt with 40,000 cases affecting 115,000 children. There was not the same amount of cruelty now as there was 23 years ago, but still the facts which came under the notice of the society were appalling. A society which preserved infant life and protected children from suffering had a strong claim on all men and women who believed in the future supremacy of the race. They were anxious to extend the web of their organisation throughout the country and he hoped that the meeting would result in a further extension of their work. On the proposition of Mr. Edward Terry, who incidentally mentioned that he belonged to societies which were responsible for some 3000 children, it was unanimously agreed that a committee of the National Society for the Prevention of Cruelty to Children should be formed for the Strand division.
